Contents

I Introduction **21**

II Definitions **24**

1 Algebra **25**
1.1 * . . . 25
1.2 Algebraic . . . 25
1.3 Algebraic structure . . . 25
1.3.1 * . . . 26
1.3.2 Fundamental theorem of algebra . . . 26
1.4 Modular arithmetic . . . 26
1.4.1 * . . . 26
1.4.2 Modulus . . . 26
1.4.2.1 * . . . 26

2 Bind **27**
2.1 * . . . 27

3 Category theory **28**
3.1 * . . . 28
3.2 Abelian category . . . 29
3.2.1 * . . . 29
3.3 Composition . . . 30
3.3.1 * . . . 30
3.4 Endofunctor category . . . 30
3.5 Functor . . . 30
3.5.1 * . . . 31
3.5.2 Power set functor . . . 31
3.5.2.1 * . . . 31
3.5.2.2 Power set functor laws . . . 31
3.5.2.3 Lift . . . 32
3.5.2.4 Power set functor is a free monad . . . 32
3.5.3 Functorial . . . 32
3.5.4 Forgetful functor . . . 32
3.5.4.1 * . . . 32
3.5.5 Identity functor . . . 32
3.5.6 Endofunctor . . . 33
3.5.6.1 * . . . 33
3.5.7 Applicative functor . . . 33
3.5.7.1 * . . . 33
3.5.7.2 Applicative law . . . 34
3.5.7.3 * . . . 34
3.5.7.4 Applicative function . . . 34
3.5.7.5 Special applicatives . . . 35

- 3.5.7.6 Monad . . . 36
- 3.5.7.7 Alternative type class . . . 49
- 3.5.7.8 «<=*>=»> . . . 49
- 3.5.8 Monoidal functor . . . 50
- 3.5.9 Fusion . . . 50
- 3.5.10 «<=$>=»> . . . 50
- 3.5.11 Multifunctor . . . 50
- 3.5.11.1 * . . . 50
- 3.5.12 * . . . 50
- 3.6 Hask category . . . 51
- 3.6.1 * . . . 51
- 3.7 Magma . . . 51
- 3.7.1 Mag category . . . 51
- 3.7.1.1 * . . . 51
- 3.7.2 Semigroup . . . 51
- 3.7.2.1 * . . . 52
- 3.7.2.2 Monoid . . . 52
- 3.8 Morphism . . . 53
- 3.8.1 * . . . 54
- 3.8.2 Homomorphism . . . 54
- 3.8.2.1 * . . . 54
- 3.8.3 Identity morphism . . . 54
- 3.8.3.1 Identity . . . 54
- 3.8.3.2 Identity function . . . 55
- 3.8.4 Monomorphism . . . 55
- 3.8.4.1 * . . . 55
- 3.8.5 Epimorphism . . . 55
- 3.8.5.1 * . . . 55
- 3.8.6 Isomorphism . . . 56
- 3.8.6.1 * . . . 56
- 3.8.6.2 Lax . . . 56
- 3.8.7 Endomorphism . . . 56
- 3.8.7.1 Automorphism . . . 56
- 3.8.7.2 * . . . 57
- 3.8.8 Catamorphism . . . 57
- 3.8.8.1 * . . . 57
- 3.8.8.2 Catamorphism law . . . 57
- 3.8.8.3 Anamorphism . . . 58
- 3.8.9 Kernel . . . 58
- 3.8.9.1 Kernel homomorphism . . . 58
- 3.9 Set category . . . 58
- 3.10 Natural transformation . . . 58
- 3.10.1 * . . . 60
- 3.10.2 Natural transformation component . . . 60
- 3.10.2.1 * . . . 60
- 3.10.3 Natural transformation in Haskell . . . 60
- 3.10.4 Cat category . . . 60
- 3.10.4.1 * . . . 61
- 3.10.4.2 Bicategory . . . 61
- 3.11 Category dual . . . 61
- 3.11.1 Coalgebra . . . 61
- 3.12 Thin category . . . 62
- 3.12.1 * . . . 62
- 3.13 Commuting diagram . . . 62
- 3.13.1 * . . . 62

3.14 Universal construction . . . 62
3.14.1 * . . . 62
3.15 Product . . . 63
3.15.1 * . . . 63
3.16 Coproduct . . . 63
3.16.1 * . . . 63
3.17 Free object . . . 63
3.18 Internal category . . . 64
3.19 Hom set . . . 64
3.19.1 * . . . 64
3.19.2 Hom-functor . . . 64
3.19.3 Exponential object . . . 64
3.19.3.1 * . . . 65
3.19.3.2 Enriched category . . . 65

4 Data type 66
4.1 * . . . 66
4.2 Actual type . . . 66
4.3 Algebraic data type . . . 66
4.3.1 * . . . 66
4.4 Cardinality . . . 66
4.4.1 * . . . 66
4.5 Data constant . . . 67
4.6 Data constructor . . . 67
4.7 data declaration . . . 67
4.8 Dependent type . . . 67
4.8.1 * . . . 67
4.9 Gen type . . . 67
4.10 Higher-kinded data type . . . 67
4.10.1 * . . . 67
4.11 newtype declaration . . . 68
4.12 Principal type . . . 68
4.13 Product data type . . . 68
4.13.1 * . . . 68
4.13.2 Sequence . . . 68
4.13.2.1 * . . . 69
4.13.2.2 List . . . 69
4.14 Proxy type . . . 69
4.15 Static typing . . . 70
4.16 Structural type . . . 70
4.16.1 * . . . 70
4.17 Structural type system . . . 70
4.17.1 * . . . 70
4.18 Sum data type . . . 70
4.19 Type alias . . . 70
4.20 Type class . . . 70
4.20.1 * . . . 70
4.20.2 Arbitrary type class . . . 71
4.20.2.1 Arbitrary function . . . 71
4.20.3 CoArbitrary type class . . . 71
4.20.3.1 * . . . 71
4.20.4 Typeable type class . . . 71
4.20.4.1 * . . . 71
4.20.5 Type class inheritance . . . 71
4.20.6 Derived instance . . . 72

4.20.6.1 * . . . 72
4.21 Type constant . . . 72
4.22 Type constructor . . . 73
4.23 type declaration . . . 73
4.24 Typed hole . . . 73
4.24.1 * . . . 73
4.25 Type inference . . . 73
4.25.1 * . . . 73
4.26 Type class instance . . . 73
4.27 Type rank . . . 73
4.27.1 * . . . 74
4.28 Type variable . . . 74
4.29 Unlifted type . . . 74
4.29.1 * . . . 74
4.30 Data structure . . . 75
4.30.1 Cons cell . . . 75
4.30.2 Construct . . . 75
4.30.2.1 * . . . 75
4.30.3 Leaf . . . 75
4.30.4 Node . . . 75
4.31 Linear type . . . 75
4.31.1 * . . . 75
4.32 NonEmpty list data type . . . 75
4.33 Session type . . . 76
4.34 Binary tree . . . 76
4.35 Bottom value . . . 76
4.35.1 * . . . 76
4.36 Bound . . . 76
4.36.1 * . . . 76
4.37 Constructor . . . 76
4.37.1 * . . . 76
4.38 Context . . . 77
4.38.1 * . . . 77
4.39 Inhabit . . . 77
4.40 Maybe . . . 77
4.40.0.1 * . . . 77
4.41 Expected type . . . 77
4.42 ADT . . . 77
4.43 Concrete type . . . 77
4.44 Type punning . . . 78
4.45 Kind . . . 78
4.45.1 * . . . 78
4.46 IO . . . 78

5 Declaration **79**

6 Differential operator **80**
6.1 * . . . 80

7 Dispatch **81**

8 Effect **82**

9 Evaluation **83**

10 Expression 84
10.1 * 84
10.2 Closed-form expression 84
10.3 RHS 84
10.4 LHS 84
10.5 Redex 85
10.6 Concatenate 85
10.7 Alpha equivalence 85
10.8 Ground expression 85
10.8.1 * 85
10.9 Variable 85
10.9.1 * 85

11 First-class 86

12 Function 87
12.1 * 87
12.2 Arity 88
12.3 Bijection 88
12.3.1 * 88
12.4 Combinator 88
12.5 Function application 89
12.5.1 * 89
12.6 Function body 89
12.7 Function composition 89
12.7.1 * 89
12.8 Function head 89
12.9 Function range 90
12.10 Higher-order function 90
12.10.1 * 90
12.10.2 Fold 90
12.11 Injection 90
12.11.1 * 91
12.12 Partial function 91
12.13 Purity 91
12.13.1 * 91
12.14 Pure function 91
12.15 Sectioning 91
12.16 Surjection 91
12.16.1 * 92
12.17 Unsafe function 92
12.17.1 * 92
12.18 Variadic 92
12.19 Domain 92
12.20 Codomain 92
12.21 Open formula 92
12.22 Recursion 92
12.22.1 * 92
12.22.2 Base case 93
12.22.3 Tail recursion 93
12.22.4 Polymorphic recursion 93
12.22.4.1 * 93
12.23 Free variable 93
12.24 Closure 93
12.24.1 * 93

12.25 Parameter . . . 93
12.25.1 * . . . 94
12.26 Partial application . . . 94
12.26.1 * . . . 94
12.27 Well-formed formula . . . 94
12.27.1 * . . . 94

13 Homotopy **95**
13.1 * . . . 95

14 Lambda calculus **96**
14.1 * . . . 96
14.2 Lambda cube . . . 96
14.2.1 * . . . 97
14.3 Lambda function . . . 97
14.3.1 * . . . 97
14.3.2 Anonymous lambda function . . . 97
14.3.2.1 * . . . 97
14.4 β-reduction . . . 97
14.4.1 * . . . 97
14.4.2 β-normal form . . . 97
14.4.2.1 * . . . 98
14.5 Calculus of constructions . . . 98
14.5.1 * . . . 98
14.6 Curry–Howard correspondence . . . 98
14.6.1 * . . . 98
14.7 Currying . . . 98
14.7.1 * . . . 99
14.8 Hindley–Milner type system . . . 99
14.8.1 * . . . 99
14.9 Reduction . . . 99
14.9.1 * . . . 99
14.10 β-η normal form . . . 99
14.10.1 * . . . 99
14.11 η-abstraction . . . 99
14.11.1 * . . . 100
14.12 Lambda expression . . . 100

15 Lense **101**

16 Operation **102**
16.1 Constant . . . 102
16.2 Binary operation . . . 102
16.2.1 * . . . 102
16.3 Operator . . . 102
16.3.1 Shift operator . . . 102
16.3.1.1 * . . . 102
16.4 Infix . . . 103
16.5 Fixity . . . 103
16.5.1 * . . . 103
16.6 Zero . . . 103

17 Permutation **104**

18 Phrase **105**

19 Point-free **106**
19.1 * . . . 106
19.2 Blackbird . . . 106
19.2.1 * . . . 106
19.3 Swing . . . 107
19.4 Squish . . . 107

20 Polymorphism **108**
20.1 * . . . 108
20.2 Levity polymorphism . . . 108
20.3 Parametric polymorphism . . . 108
20.3.1 Rank-1 polymorphism . . . 108
20.3.1.1 * . . . 108
20.3.2 Let-bound polymorphism . . . 109
20.3.3 Constrained polymorphism . . . 109
20.3.3.1 Ad hoc polymorphism . . . 109
20.3.4 Impredicative polymorphism . . . 109
20.3.4.1 * . . . 109
20.3.5 Higher-rank polymorphism . . . 109
20.3.5.1 * . . . 110
20.4 Subtype polymorphism . . . 110
20.5 Row polymorphism . . . 110
20.6 Kind polymorphism . . . 110
20.7 Linearity polymorphism . . . 111

21 Pragma **112**
21.1 LANGUAGE pragma . . . 112
21.1.1 LANGUAGE option . . . 112
21.1.1.1 * . . . 112
21.1.1.2 Useful by default . . . 112
21.1.1.3 AllowAmbiguousTypes . . . 112
21.1.1.4 ApplicativeDo . . . 112
21.1.1.5 ConstrainedClassMethods . . . 113
21.1.1.6 CPP . . . 113
21.1.1.7 DeriveFunctor . . . 113
21.1.1.8 ExplicitForAll . . . 113
21.1.1.9 FlexibleContexts . . . 113
21.1.1.10 FlexibleInstances . . . 114
21.1.1.11 GeneralizedNewtypeDeriving . . . 114
21.1.1.12 ImplicitParams . . . 114
21.1.1.13 LambdaCase . . . 114
21.1.1.14 MultiParamTypeClasses . . . 114
21.1.1.15 MultiWayIf . . . 115
21.1.1.16 OverloadedStrings . . . 115
21.1.1.17 PartialTypeSignatures . . . 115
21.1.1.18 RankNTypes . . . 115
21.1.1.19 ScopedTypeVariables . . . 116
21.1.1.20 TupleSections . . . 116
21.1.1.21 TypeApplications . . . 116
21.1.1.22 TypeSynonymInstances . . . 116
21.1.1.23 UndecidableInstances . . . 117
21.1.1.24 ViewPatterns . . . 117
21.1.1.25 DatatypeContexts . . . 117
21.1.1.26 StandaloneKindSignatures . . . 117
21.1.1.27 PartialTypeSignatures . . . 118

21.1.2 How to make a GHC LANGUAGE extension . . . 118

22 Predicative 120

23 Compositionality 121
23.1 * . . . 121

24 Ψ-combinator 122
24.1 * . . . 122

25 Quantifier 123
25.1 * . . . 123
25.2 Forall quantifier . . . 123
25.2.1 * . . . 123

26 Referential transparency 124
26.1 * . . . 124

27 Relation 125
27.1 * . . . 125

28 REPL 126

29 Semantics 127
29.1 Operational semantics . . . 127
29.2 Denotational semantics . . . 127
29.2.1 Abstraction . . . 127
29.2.1.1 * . . . 128
29.2.1.2 Leaky abstraction . . . 128
29.2.1.3 Object . . . 128
29.2.2 Ambigram . . . 129
29.2.3 Binary . . . 129
29.2.4 Arbitrary . . . 129
29.2.5 Refutable . . . 130
29.2.6 Irrefutable . . . 130
29.3 Axiomatic semantics . . . 130
29.3.1 Property . . . 130
29.3.1.1 * . . . 130
29.3.1.2 Associativity . . . 130
29.3.1.3 Left associative . . . 131
29.3.1.4 Right associative . . . 131
29.3.1.5 Non-associative . . . 131
29.3.1.6 Basis . . . 131
29.3.1.7 Commutativity . . . 132
29.3.1.8 Idempotence . . . 132
29.3.1.9 Distributive property . . . 132
29.4 Argument . . . 133
29.4.1 Argument of a function . . . 133
29.4.1.1 * . . . 133
29.5 Content word . . . 133
29.6 Ancient Greek and Latin prefixes . . . 133
29.6.1 * . . . 133
29.7 Idiom . . . 133
29.7.1 * . . . 133
29.8 Impredicative . . . 133
29.9 Context-free grammar . . . 135

29.9.1 * 135

30 Set 136
30.1 * 136
30.2 Closed set 136
30.3 Power set 136
30.4 Singleton 136
30.5 Russell's paradox 136
30.6 Cartesian product 137
30.6.1 Pullback 137
30.6.1.1 * 137

31 Shrinking 138

32 Spine 139

33 Superclass 140

34 Tensor 141
34.1 * 141

35 Testing 142
35.1 Property testing 142
35.1.1 Function property 142
35.1.2 Property testing type 142
35.1.3 Generator 142
35.1.3.1 * 143
35.1.3.2 Custom generator 143
35.1.4 Reusing test code 143
35.1.4.1 Test Commutative property 143
35.1.4.2 Test Symmetry property 143
35.1.4.3 Test Equivalence property 144
35.1.4.4 Test Inverse property 144
35.1.5 QuickCheck 144
35.1.5.1 Manual automation with QuickCheck properties 144
35.2 Write tests algorithm 145

36 Uncurry 146

37 Unit 147

38 Nullary 148

39 Logic 149
39.1 Proposition 149
39.1.1 * 149
39.1.2 Atomic proposition 149
39.1.2.1 * 149
39.1.3 Compound proposition 149
39.1.3.1 * 149
39.1.4 Propositional logic 149
39.1.4.1 * 150
39.1.4.2 First-order logic 150
39.2 Logical connective 150
39.2.1 * 150
39.2.2 Conjunction 150
39.2.3 Disjunction 151

39.3 Predicate 151
39.4 Statement 151
39.4.1 * 151
39.5 Iff 152

40 Haskell structures 153
40.1 Pattern match 153
40.1.1 As-pattern 153
40.1.1.1 * 153
40.1.2 Wild-card 153
40.1.2.1 * 153
40.1.3 Case 154
40.1.4 Guard 154
40.1.4.1 * 154
40.1.5 Pattern guard 154
40.1.5.1 * 155
40.1.6 Lazy pattern 155
40.1.6.1 * 155
40.1.7 Pattern binding 155
40.1.7.1 * 155
40.2 Smart constructor 155
40.3 Level of code 156
40.3.1 * 156
40.3.2 Type level 156
40.3.2.1 Type level declaration 156
40.3.2.2 Type check 156
40.3.3 Term level 157
40.3.4 Compile level 157
40.3.4.1 * 157
40.3.5 Runtime level 157
40.3.6 Kind level 157
40.3.6.1 Kind check 157
40.4 Orphan type instance 158
40.5 Undefined 158
40.6 Hierarchical module name 158
40.6.1 * 163
40.7 import 163
40.8 Let 164
40.8.1 * 164
40.9 Where 164
40.9.1 * 165
40.10Reserved word 165
40.10.1 * 165
40.11Haskell Language Report 165
40.11.1 * 165
40.12Haskell' 165
40.12.1 * 165

41 Computer science 166
41.1 Guerrilla patch 166
41.1.1 Monkey patch 166
41.2 Interface 166
41.3 Module 166
41.4 Scope 166
41.4.1 Dynamic scope 166

41.4.2 Lexical scope . . . 166
41.4.2.1 * . . . 167
41.4.3 Local scope . . . 167
41.4.3.1 * . . . 167
41.5 Shadowing . . . 167
41.6 Syntatic sugar . . . 167
41.7 System F . . . 167
41.7.1 * . . . 167
41.8 Tail call . . . 167
41.9 Thunk . . . 167
41.10 Application memory . . . 168
41.11 Turing machine . . . 168
41.11.1 Turing complete . . . 168

(add-hook 'org-font-lock-set-keywords-hook #'org-hidden-links-hook-function)
```

`SCHT`: and metadata in `:properties:` - of my `org-drill` practices, please just run `org-drill-strip-all-data`.

Part II

Definitions

Chapter 1

Algebra

al-jabr - assemble parts.
A system of parts based on given axioms (properties).

—

a. Abstract algebra - the study of number systems and operations within them.

b. Algebra - vector space over a field with a multiplication.

c. Algebra - a set with its algebraic structure.

1.1 *

Algebras

1.2 Algebraic

Composite from simple parts.
Also: Algebraic data type.

1.3 Algebraic structure

Algebraic structure on a set (called carrier set or underlying set) is a collection of finitary operations on that set.
The set with this structure is also called an algebra.

Algebraic structures include groups, rings, fields, and lattices. More complex structures can be defined by introducing multiple operations, different underlying sets, or by altering the defining axioms. Examples of more complex algebraic structures include vector spaces, modules, and algebras.

Table 1.1: Algebraic structures

	Closure	Associativity	Identity	Invertability	Commutativity
Semigroupoid		✓			
Small Category		✓	✓		
Groupoid		✓	✓	✓	
Magma	✓				
Quasigroup	✓			✓	
Loop	✓		✓	✓	
Semigroup	✓	✓			
Inverse Semigroup	✓	✓		✓	
Monoid	✓	✓	✓		
Group	✓	✓	✓	✓	
Abelian group	✓	✓	✓	✓	✓
Ring	✓	✓	✓	✓	under $+$

1.3.1 *

Algebraic structures

1.3.2 Fundamental theorem of algebra

Any non-constant single-variable polynomial with complex coefficients has at least one complex root.

From this definition follows property that the field of complex numbers is algebraically closed.

1.4 Modular arithmetic

System for integers where numbers wrap around the certain values (single - *modulus*, plural - *moduli*).

Example - 12-hour clock.

1.4.1 *

Clock arithmetic

1.4.2 Modulus

Special numbers where arithmetic wraps around in modular arithmetic.

1.4.2.1 *

Moduli - plural.

Chapter 2

Bind

Establishing equality between two objects.

Most often:

- equating variable to a value.
- equating parameter of a function to an argument (variable/value/function). This term often is equated to applying argument to a function, which includes β-reduction.

2.1 *

Binds
Binding
Bindings

Chapter 3

Category theory

Category $\mathcal{C}$ consists of the basis:

Primitives:

a. Objects - $a^{\mathcal{C}}$. A node. Object of some type. Often sets, than it is Set category.

b. Arrows - $(a, b)^{\mathcal{C}}$ (AKA morphisms mappings).

c. Arrow (morphism) composition - binary operation: $(a, b)^{\mathcal{C}} \circ (b, c)^{\mathcal{C}} \equiv (a, c)^{\mathcal{C}} \mid \forall a, b, c \in \mathcal{C}$. AKA principle of compositionality for arrows.

Properties (or axioms):

a. Associativity of morphisms: $h \circ (g \circ f) \equiv (h \circ g) \circ f \quad | \quad f_{a \to b}, g_{b \to c}, h_{c \to d}$.

b. Every object has (two-sided) identity morphism (& in fact - exactly one): $1_x \circ f_{a \to x} \equiv f_{a \to x}, \quad g_{x \to b} \circ 1_x \equiv g_{x \to b} \quad | \quad \forall x \ \exists 1_x, \forall f_{a \to x}, \forall g_{x \to b}$.

c. Principle of compositionality.

From these axioms, can be proven that there is exactly one identity morphism for every object.

Object and morphism are complete abstractions for anything.
In majority of cases under object is a state and morphism is a change.

3.1 *

Category
Categories

3.2 Abelian category

Generalised category for homological algebra (having a possibility of basic constructions and techniques for it).

Category which:

- has a zero object,
- has all binary biproducts,
- has all kernel's and cokernels,
- (it has all pullbacks and pushouts)
- all monomorphism's and epimorphism's are normal.

Abelian category is very stable; for example they are regular and they satisfy the snake lemma. The class of Abelian categories is closed under several categorical constructions.

There is notion of Abelian monoid (AKS Commutative monoid) and Abelian group (Commutative group).

Basic examples of *:

- category of Abelian groups
- category of modules over a ring.

* are widely used in algebra, algebraic geometry, and topology.

* has many constructions like in categories of modules:

- kernels
- exact sequences
- commutative diagrams

* has disadvantage over category of modules. Objects do not necessarily have elements that can be manipulated directly, so traditional definitions do not work. Methods must be supplied that allow definition and manipulation of objects without the use of elements.

3.2.1 *

Abelian categories

3.3 Composition

Axiom of Category.

3.3.1 *

Composable
Compositions

3.4 Endofunctor category

From the name, in this Category:

- objects of End are Endofunctors $E^{\mathcal{C} \to \mathcal{C}}$

- morphisms are natural transformations between endofunctors

3.5 Functor

* full translation (map) of one category into another.
Translating objects and morphisms (as input can take morphism or object).

* - forgetful - discards part of the structure.
* - faithful - fully preserves all morphisms - injective on Hom-sets.
* - full - translation of morphisms fully covers all the morphisms between according objecs in the target categoty.

For Functor type class or fmap - see Power set functor.

Functor properties (axioms):

- $F^{\mathcal{C} \to \mathcal{D}}(a) \quad | \quad \forall a^{\mathcal{C}}$ - every source object is mapped to object in target category

- $\overrightarrow{(F^{\mathcal{C} \to \mathcal{D}}(a), F^{\mathcal{C} \to \mathcal{D}}(b))}^{\mathcal{D}} \quad | \quad \forall \overrightarrow{(a,b)}^{\mathcal{C}}$ - every source morphism is mapped to target category morphism between corresponding objects

- $F^{\mathcal{C} \to \mathcal{D}}(\overrightarrow{g}^{\mathcal{C}} \circ \overrightarrow{f}^{\mathcal{C}}) = F^{\mathcal{C} \to \mathcal{D}}(\overrightarrow{g}^{\mathcal{C}}) \circ F^{\mathcal{C} \to \mathcal{D}}(\overrightarrow{f}^{\mathcal{C}}) \quad | \quad \forall y = \overrightarrow{f}^{\mathcal{C}}(x), \forall \overrightarrow{g}^{\mathcal{C}}(y)$ - composition of morphisms translates directly (tautologically goes from other two)

These axioms guarantee that composition of functors can be fused into one functor with composition of morphisms. This process called fusion.

In Haskell this axioms have form:

```
fmap id = id
fmap (f . g) = fmap f . fmap g
```

Since * is 1-1 mapping of initial objects - it is a memoizable dictionary with cardinality of initial objects. Also in Hask category functors are obviously endofunctors ∴ they are special kinds of containers for the parametric values (AKA product type). In Haskell product type * are endofunctors from polymorphic type into a functor wrapper of a polymorphic type.

* translates in one direction, and does not provide algorythm of reversing itself or retriving the parametric value.

3.5.1 *

Functors

3.5.2 Power set functor

$\mathcal{P}^{\mathcal{S} \to \mathcal{P}(\mathcal{S})}$

* - functor from set S to its power set $\mathcal{P}(S)$.

Functor type class in Haskell defines a * and allows to do function application inside type structure layers (denoted f or m). IO is also such structure.
Power set is unique to the set, * is unique to the category (data type).
* embodies in itself any endofunctor. It is easily seen from Haskell definition - that the * is the polymorphic generalization over any endofunctor in a category. Application of a function to * gives a particular endofunctor (see Hask category).

```
class Functor f where
  fmap :: (a -> b) -> f a -> f b
```

Functor instance must be of kind `( * -> * )`, so instance for higher-kinded data type must be applied until this kind.

Composed * can lift functions through any layers of structures that belong to Functor type class.

* can be used to filter-out error cases (Nothing & Left cases) in Maybe, Either and related types.

3.5.2.1 *

fmap
Functor type class

3.5.2.2 Power set functor laws

Type instance of functor should abide this laws:

a. *

Functor laws

b. Power set functor identity law

```
fmap id == id
```

c. Power set functor composition law

```
fmap (f.g) == fmap f . fmap g
```

In words, it is if several functions are composed and then fmap is applied on them - it should be the same as if functions was fmapped and then composed.

3.5.2.3 Lift

```
fmap :: (a -> b) -> (f a -> f b)
```

Functor takes function `a -> b` and returns a function `f a -> f b` this is called lifting a function. Lift does a function application through the data structure.

a. *

Lifting

3.5.2.4 Power set functor is a free monad

Since:

- $\forall e \in S : \exists \{e\} \in \mathcal{P}(S) \vDash \forall e \in S : \exists (e \to \{e\}) \equiv unit$
- $\forall \mathcal{P}(S) : \mathcal{P}(S) \in \mathcal{P}(S) \vDash \forall \mathcal{P}(S) : \exists (\mathcal{P}(\mathcal{P}(S)) \to \mathcal{P}(S)) \equiv join$

3.5.3 Functorial

Corresponds to functor laws.

3.5.4 Forgetful functor

Functor that forgets part or all of what defines structure in domain category.
$F^{\mathbf{Grp} \to \mathbf{Set}}$ that translates groups into their underlying sets.
Constant functor is another example.

3.5.4.1 *

Forgetful

3.5.5 Identity functor

Maps all category to itself. All objects and morphisms to themselves.

Denotation:
$1^{\mathcal{C} \to \mathcal{C}}$

3.5.6 Endofunctor

Is a functor which source (domain) and target (codomain) are the same category.

$F^{\mathcal{C}\to\mathcal{C}}, E^{\mathcal{C}\to\mathcal{C}}$

3.5.6.1 *

Endofunctors

3.5.7 Applicative functor

* - Computer science term. Category theory name - lax monoidal functor. And in category *Set*, and so in category *Hask* all applicatives and monads are strong (have tensorial strength).

* - sequences functorial computations (plain functors can't).

```
(<*>) :: f (a -> b) -> f a -> f b
```

Requires Functor to exist.
Requires Monoidal structure.

Has monoidal structure rules, separated form function application inside structure.

Data type can have several applicative implementations.

Standard definition:

```
class Functor f => Applicative f
 where
  (<*>) :: f (a -> b) -> f a -> f b
  pure :: a -> f a
```

`pure` - if a functor, identity Kleisli arrow, natural transformation.

Composition of * always produces *, contrary to monad (monads are not closed under composition).

`Control.Monad` has an old function `ap` that is old implementation of `<*>`:

```
ap :: Monad m => m (a -> b) -> m a -> m b
```

3.5.7.1 *

Applicative
Applicatives
Applicative functors

3.5.7.2 Applicative law

3.5.7.3 *

Applicative laws

a. Applicative identity law

```
pure id <*> v = v
```

b. Applicative composition law Function composition works regularly.

```
pure (.) <*> u <*> v <*> w = u <*> (v <*> w)
```

c. Applicative homomorphism law Internal function application doesn't change the structure around values.

```
pure f <*> pure x = pure (f x)
```

d. Applicative interchange law On condition that internal order of evaluation is preserved - order of operands is not relevant.

```
u <*> pure y = pure ($ y) <*> u
```

3.5.7.4 Applicative function

a. liftA*

   a. liftA Essentially a fmap.

   ```
   :type liftA
   liftA :: Applicative f => (a -> b) -> f a -> f b
   ```

   Lifts function into applicative function.

   b. liftA2 Lifts binary function across two Applicative functors.

   ```
   liftA2 :: Applicative f => (a -> b -> c) -> f a -> f b -> f c
   ```

   ```
   liftA2 f x y == pure f <*> x <*> y
   ```

   c. «<liftA2 (<*>)»> liftA2 (<*>) is pretty useful. It can lift binary operation through the two layers:
   It is two-layer Applicative.

   ```
   liftA2 :: Applicative f => (     a        ->  b  ->  c ) -> f       a          ->  f    b    -
   <*> :: Applicative f =>     (f  (a -> b) -> f a -> f b)
   liftA2 (<*>) :: (Applicative f1, Applicative f2) =>      f1 (f2 (a -> b)) -> f1 (f2 a) -
   ```

   d. «<liftA2 (liftA2 (<*>))»> liftA2 (<*>) 3-layer version.

   e. liftA3 liftA2 3-parameter version.

   ```
   liftA3 f x y z == pure f <*> x <*> y <*> z
   ```

b. Conditional applicative computations

```
when :: Applicative f => Bool -> f () -> f ()
```

Only when `True` - perform an applicative computation.

```
unless :: Applicative f => Bool -> f () -> f ()
```

Only when `False` - perform an applicative computation.

3.5.7.5 Special applicatives

a. Identity applicative

```
-- Applicative f =>
-- f ~ Identity
type Id = Identity
instance Applicative Id
  where
    pure :: a -> Id a
    (<*>) :: Id (a -> b) -> Id a -> Id b

mkId = Identity
xs = [1, 2, 3]

const <$> mkId xs <*> mkId xs'
-- [1,2,3]
```

b. Constant applicative It holds only to one value. The function does not exist and last parameter is a phantom.

```
-- Applicative f =>
-- f ~ Constant e
type C = Constant
instance Applicative C
 where
  pure :: a -> C e a
  (<*>) :: C e (a -> b) -> C e a -> C e b
```

c. Maybe applicative "There also can be no function at all."

If function might not exist - embed `f` in Maybe structure, and use Maybe applicative.

```
-- f ~ Maybe
type M = Maybe
pure :: a -> M a
(<*>) :: M (a -> b) -> M a -> M b
```

d. Either applicative `pure` is `Right`.
Defaults to `Left`.
And if there is two `Left`'s - to Left of the first argument.

e. Validation applicative The Validation data type isomorphic to Either, but has accumulative Applicative on the Left side.
Validation data type is not a monad. Validation is an example of, "An applicative functor

that is not a monad."
While Either monad on `Left` case just drops computation and returns this first `Left`.
Monad needs to process the result of computation - it requires to be able to process all Left error statement cases for Validation, it is or non-terminaring Monad or one which is impossible to implement in polymorphic way with Validation.

3.5.7.6 Monad

$\mu\acute{}\nu o\varsigma$ *monos* sole
$\mu o\nu\acute{}\delta\alpha$ *monáda* unit

* - monoid in endofunctor category with η (unit) and μ (join) natural transformations.

Monad on $\mathcal{C}$ is $\{E^{\mathcal{C}\to\mathcal{C}}, \eta, \mu\}$:

- $E^{\mathcal{C}\to\mathcal{C}}$ - is an endofunctor
- two natural transformations, $1^c \to E$ and $E \circ E \to E$:
  - $\eta^{1^{\mathcal{C}}\to E} = unit^{Identity\to E}(x) = f^{x\to E(x)}(x)$
  - $\mu^{(E\circ E)\to E} = join^{(E\circ E)\to(Identity\circ E)}(x) = |y = E(x)| = f^{E(y)\to y}(y)$

where:

- $\mathcal{C}$ is a category
- $1^{\mathcal{C}}$ denotes the $\mathcal{C}$ identity functor
- $(E \circ E)$ - endofunctor $\mathcal{C} \to \mathcal{C}$

Definition with $\{E^{\mathcal{C}\to\mathcal{C}}, \eta, \mu\}$ (in Hask: $(\{e\ ::\ f\,a\ \to\ f\,b,\ pure,\ join\})$) - is classic categorical, in Haskell minimal complete definition is $\{fmap, pure, (>>=)\}$.

If there is a structure S, and a way of taking object x into S and a way of collapsing $S \circ S$ - there probably a monad.

Mostly monads used for sequencing actions (computations) (that looks like imperative programming), with ability to dependend on previous chains. Note if monad is commutative - it does not order actions.

Monad can shorten/terminate sequence of computations. It is implemented inside Monad instance. For example Maybe monad on Nothing drops chain of computation and returns Nothing.

* inherits the Applicative instance methods:

```
import Control.Monad (ap)
return == pure
ap == (<*>) -- + Monad requirement
```

Table 3.1: Monad in mathematics and Haskell

Math	Meaning	Cat/Fctr	$X \in C$	Type	Haskell
Id	endofunctor "Id"	$C \to C$	$X \to Id(X)$	$a \to a$	id
E	endofunctor "monad"	$C \to C$	$X \to E(X)$	$m\ a \to m\ b$	fmap
η	natural transformation "unit"	$Id \to E$	$Id(X) \to E(X)$	$a \to m\ a$	pure
μ	natural transformation "multiplication"	$E \circ E \to E$	$E(E(X)) \to E(X)$	$m\ (m\ a) \to m\ a$	join

Internals of Monad are Haskell data types, and as such - they can be consumed any number of times.

Composition of monadic types does not always results in monadic type.

a. *

   Monads
   Monadic

b. Monad law Monad corresponds to functor laws & applicative laws and additionally:

   a. * Monad laws

   b. Monad left identity law

   ```
   pure x >>= f == f x
   ```

   Explanation:

   ```
   >>= :: Monad f =>     f a  -> (a -> f b) -> f b
                     pure x >>=      f       == f x
   ```

   Rule that »= must get first argument structure internals and apply to the function that is the second argument.

   c. Monad right identity law

   ```
   f >>= pure == f
   ```

   Explanation:

   ```
   >>= :: Monad f => f a  -> (a -> f b) -> f b
                     f   >>=     pure    == f
   ```

   AKA it is a tacit description of a monad bind as endofunctor.

   d. Monad associativity law

   ```
   (m >>= f) >>= g == m >>= (\ x -> f x >>= g)
   ```

c. Monad type class

```
class Applicative m => Monad m where
  (>>=) :: m a -> (a -> m b) -> m b
  (>>) :: m a -> m b -> m b
  return :: a -> m a
```

a. MonadPlus type class Is a monoid over monad, with additional rules.
The precise set of rules (properties) not agreed upon. Class instances obey *monoid* & *left zero* rules, some additionally obey *left catch* and others *left distribution*.

Overall there * currently reforms (MonadPlus reform proposal) in several smaller nad strictly defined type classes.

Subclass of an Alternative.

a. *
Monadplus

d. Functor -> Applicative -> Monad progression

```
<$> :: Functor     f =>   (a -> b)   -> f a -> f b
<*> :: Applicative f => f (a -> b)   -> f a -> f b
=<< :: Monad       f =>   (a -> f b) -> f a -> f b
```

`pure` & `join` are Natural transformations for the `fmap`.

e. Monad function

a. Return function

```
return == pure
```

Nonstrict.

b. Join function

```
join :: Monad m => m (m a) -> m a
```

Generales knowledge of `concat`.

Kleisli composition that flattens two layers of structure into one.

The way to express ordering in lambda calculus is to nest.

a. *
join

b. join . fmap == (=«)

```
-- b = f b
fmap        :: Monad f => (a -> f b) -> f a -> f (f b)
join        :: Monad f =>                      f (f a) -> f a
join . fmap :: Monad f => (a -> f b) -> f a            -> f b
flip    >>= :: Monad f => (a -> f b) -> f a            -> f b
```

c. Bind function

```
>>=         :: Monad f => f a -> (a -> f b) -> f b
join . fmap :: Monad f => (a -> f b) -> f a -> f b
```

Nonstrict.

The most ubiqutous way to »= something is to use Lambda function:

```
getLine >>= \name -> putStrLn "age pls:"
```

Also very neet way is to bundle and handle Monad - is to bundle it with bind, and leave applied partially.
And use that partial bundle as a function - every evaluation of the function would trigger evaluation of internal Monad structure. Thumbs up.

```
printOneOf :: Bool -> IO ()
printOneOf False = putStr "1"
printOneOf  True = putStr "2"

quant [U+2237] (Bool → IO b) → IO b
quant = (>>=) (randomRIO (False, True))

recursePrintOneOf [U+2237] Monad m ⇒ (t → m a) → t → m b
recursePrintOneOf f x = (f x) >> (recursePrintOneOf f x)

main :: IO ()
main = recursePrintOneOf (quant) $ printOneOf
```

a. *
Monadic extend
Monadic bind
Monad bind
Binder
Binder function

a. (»=)
b. »=
c. (=«)
d. =«

d. Sequencing operator (») == (*>): Discard any resulting value of the action and sequence next action.
Applicative has a similar operator.

```
(>>) :: m a -> m b -> m b
(*>) :: f a -> f b -> f b
```

e. Monadic versions of list functions

```
sequence :: (Traversable t, Monad m) => t (m a) -> m (t a)
```

Sequence gets the traversable of monadic computations and swaps it into monad computation of taverse. In the result the collection of monadic computations turns into one long monadic computation on traverse of data.

If some step of this long computation fails - monad fails.

```
mapM :: (Traversable t, Monad m) => (a -> m b) -> t a -> m (t b)
```

`mapM` gets the AMB function, then takes traversable data. Then applies AMB function to traversable data, and returns converted monadic traversable data.

```
foldM :: (Foldable t, Monad m) => (b -> a -> m b) -> b -> t a -> m b
foldl ::  Foldable t          => (b -> a ->   b) -> b -> t a ->   b
```

* is a monadic `foldl`.

`b` is initial comulative value, `m b` is a comulative bank.
Right folding achieved by reversing the input list.

```
filterM :: Applicative m => (a -> m Bool) -> [a] -> m [a]
filter ::                   (a ->   Bool) -> [a] ->   [a]
```

Take Boolean monadic computation, filter the list by it.

```
zipWithM :: Applicative m => (a -> b -> m c) -> [a] -> [b] -> m [c]
zipWith  ::                  (a -> b ->   c) -> [a] -> [b] ->   [c]
```

Take monadic combine function and combine two lists with it.

```
msum :: (Foldable t, MonadPlus m) => t (m a) -> m a
sum  :: (Foldable t, Num a)       => t    a  ->   a
```

f. liftM*

a. liftM Essentially a fmap.

```
liftM :: Monad m => (a -> b) -> m a -> m b
```

Lifts a function into monadic equivalent.

b. liftM2 Monadic liftA2.

```
liftM2 :: Monad m => (a -> b -> c) -> m a -> m a -> m c
```

Lifts binary function into monadic equivalent.

f. Comonad Category $\mathcal{C}$ comonad is a monad of opposite category $\mathcal{C}^{op}$.

g. Kleisli arrow Morphism that while doing computation also adds monadic-able structure.

```
a -> m b
```

a. *

Kleisli arrows
Kleisli morphism
Kleisli morphisms

h. Kleisli composition Composition of Kleisli arrows.

```
(<=<) :: Monad m => (b -> m c) -> (a -> m b) -> a -> m c infixr 1
;; compare
(.)   ::            (b ->   c ) -> (a ->   b ) -> a ->   c
```

Often used left-to-right version:

```
(>=>) :: Monad m => (a -> m b) -> (b -> m c) -> a -> m c
;; compare
(>>=) :: Monad m =>       m a   -> (a -> m b)       -> m b
```

Which allows to replace monadic bind chain with Kleisli composition.

```
f1 arg >>= f2 >>= f3
==
f1 >=> f2 >=> f3 $ arg
==
f3 <=< f2 <=< f1 $ arg
```

i. Kleisli category Category $\mathcal{C}$, [U+2329] $E, \overrightarrow{\eta}, \overrightarrow{\mu}$ [U+232A] monad over $\mathcal{C}$.

Kleisli category $\mathcal{C}_T$ of $\mathcal{C}$:

$$\begin{aligned} \mathrm{Obj}(\mathcal{C}_T) &= \mathrm{Obj}(\mathcal{C}) \\ \mathrm{Hom}_{\mathcal{C}_T}(x, y) &= \mathrm{Hom}_{\mathcal{C}}(x, E(y)) \end{aligned}$$

j. Special monad

a. Identity monad Wraps data in the Identity constructor.

Useful: Creates monads from monad transformers.

Bind: Applies internal value to the bound function.

Code:

```
newtype Identity a = Identity { runIdentity :: a }

-- coerse is a function that directly moves data between type aliases
instance Functor Identity where
  fmap     = coerce

instance Applicative Identity where
  pure     = Identity
  (<*>)    = coerce

instance Monad Identity where
  m >>= k  = k (runIdentity m)
```

Example:

```
-- derive the State monad using the StateT monad transformer
type State s a = StateT s Identity a
```

b. Maybe monad Something that may not be or not return a result. Any lookups into the real world, database querries.

Bind: `Nothing` input gives `Nothing` output, `Just x` input uses `x` as input to the bound function.

When some computation results in Nothing - drops the chain of computations and returns Nothing.

Zero: Nothing
Plus: result in first occurence of Just else Nothing.

Code:

```
data Maybe a = Nothing | Just a

instance Monad Maybe where
  return         = Just
  fail           = Nothing
  Nothing  >>= _ = Nothing
  (Just x) >>= f = f x

instance MonadPlus Maybe where
  mzero               = Nothing
  Nothing `mplus` x = x
  x `mplus` _         = x
```

Example:
Given 3 dictionaries:

a. Full names to email addresses,

b. Nicknames to email addresses,

c. Email addresses to email preferences.

Create a function that finds a person's email preferences based on either a full name or a nickname.

```
data MailPref = HTML | Plain
data MailSystem = ...

getMailPrefs :: MailSystem -> String -> Maybe MailPref
getMailPrefs sys name =
  do let nameDB = fullNameDB sys
         nickDB = nickNameDB sys
         prefDB = prefsDB sys
  addr <- (lookup name nameDB) `mplus` (lookup name nickDB)
  lookup addr prefDB
```

c. Either monad When computation results in `Left` - drops other computations & returns the recieved `Left`.

d. Error monad Someting that can fail, throw exceptions.

The failure process records the description of a failure. Bind function uses successful values as input to the bound function, and passes failure information on without executing the bound function.

Useful:
Composing functions that can fail. Handle exceptions, crate error handling structure.

Zero: empty error.
Plus: if first argument failed then execute second argument.

e. List monad Computations which may return 0 or more possible results.

Bind: The bound function is applied to all possible values in the input list and the resulting lists are concatenated into list of all possible results.

Useful: Building computations from sequences of non-deterministic operations.

Zero: []
Plus: (++)

a. *
[] monad

f. Reader monad Creates a read-only shared environment for computations.

The `pure` function ignores the environment, while »= passes the inherited environment to both subcomputations.

Today it is defined though ReaderT transformer:

```
type Reader r = ReaderT r Identity   -- equivalent to ((->) e), (e ->)
```

Old definition was:

```
newtype Reader e a = Reader { runReader :: (e -> a) }
```

For `(e ->)`:

- Functor is `(.)`

```
fmap :: (b -> c) -> (a -> b) -> a -> c
fmap = (.)
```

- Applicative:
  - `pure` is `const`

```
pure :: a -> b -> a
pure x _ = x
```

- `(<*>)` is:

```
(<*>) :: (a -> b -> c) -> (a -> b) -> a -> c
(<*>) f g = \a -> f a (g a)
```

- Monad:

```
(>>=) :: (a -> b) -> (b -> a -> c) -> a -> c
(>>=) m k = Reader $ \r ->
  runReader (k (runReader m r)) r

join :: (e -> e -> a) -> e -> a
join f x = f x x
```

```haskell
runReader
  :: Reader r a  -- the Reader to run
  -> r  -- an initial environment
  -> a  -- extracted final value
```

Usage:

```haskell
data Env = ...

createEnv :: IO Env
createEnv = ...

f :: Reader Env a
f = do
  a <- g
  pure a

g :: Reader Env a
g = do
  env <- ask  -- "Open the environment namespace into env"
  a <- h env  -- give env to h
  pure a

h :: Env -> a
...  -- use env and produce the result

main :: IO ()
main = do
  env <- createEnv
  a = runReader g env
  ...
```

In Haskell under normal circumstances impure functions should not directy call impure functions.
`h` is an impure function, and `createEnv` is impure function, so they should have intermediary.

g. Writer monad Computations which accumulate monoid data to a shared Haskell storage.
So * is parametrized by monoidal type.

Accumulator is maintained separately from the returned values.

Shared value modified through Writer monad methods.

* frees creator and code from manually keeping the track of accumulation.

Bind: The bound function is applied to the input value, bound function allowed to `<>` to the accumulator.

```haskell
type Writer r = WriterT r Identity
```

Example:

```haskell
f :: Monoid b => a -> (a, b)
f a = if _condition_
```

```
          then runWriter $ g a
          else runWriter do
            a1 <- h a
            pure a1

g :: Monoid b => Writer b a
g a = do
  tell _value1_  -- accumulator <> _value1_
  pure a  -- observe that accumulator stored inside monad and only a main value needs to

h :: Monoid b => Writer b a
h a = do
  tell _value2_  -- accumulator <> _value_
  pure a

runWriter :: Writer w a -> (a, w)  -- Unwrap a writer computation as a (result, accumula
                                   -- The inverse of writer.
```

`WriterT`, `Writer` unnecessarily keeps the entire logs in the memory. Use `fast-logger` for logging.

h. State monad Computations that pass-over a state.

The bound function is applied to the input value to produce a state transition function which is applied to the input state.

Pure functional language cannot update values in place because it violates referential transparency.

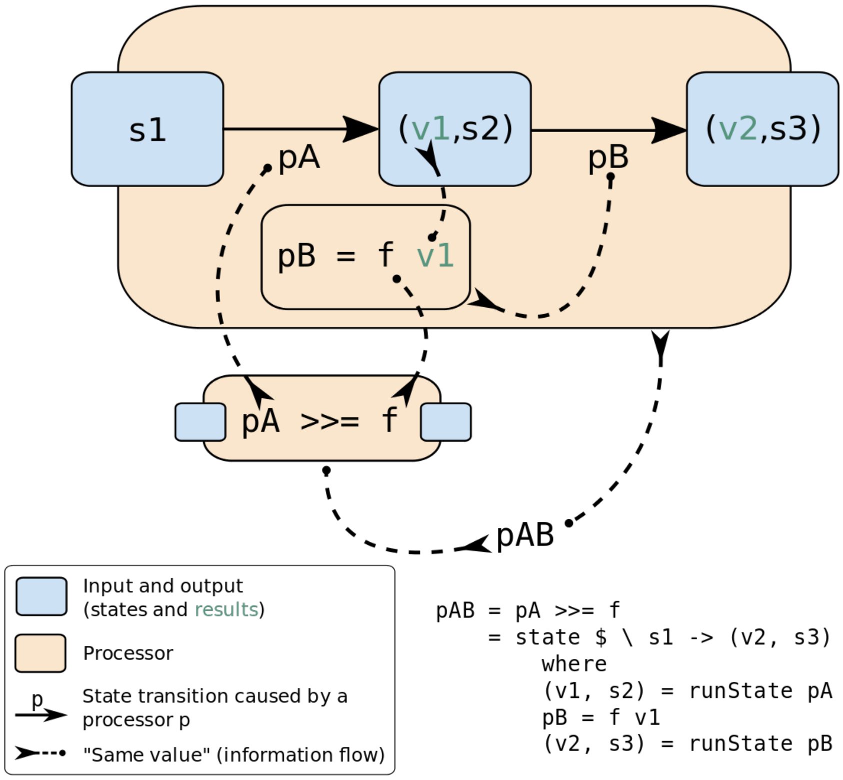
```
type State s = StateT s Identity
```

Binding copies and transforms the state parameter through the sequence of the bound functions so that the same state storage is never used twice. Overall this gives the illusion of in-place update to the programmer and in the code, while in fact the autogenerated transition functions handle the state changes.

Example type: `State st a`

`State` describes functions that consume a state and produce a tuple of result and an updated state.

Monad manages the state with the next process:



```
pAB = pA >>= f
    = state $ \ s1 -> (v2, s3)
        where
        (v1, s2) = runState pA s1
        pB = f v1
        (v2, s3) = runState pB s2
```

Where:

- f - processsor making function
- pA, pAB, pB - state processors
- sN - states
- vN - values

Bind with a processor making function from state procesor (pA) creates a new state processor (pAB).
The wrapping and unwrapping by State/runState is implicit.

k. Monad transformer * is a practical solution to the current functional programming problem about composition of monads.

Monad is not closed under compostion.
Composition of monadic types does not always results in monadic type.

Basic case: during implementation of monadic type composition, type `m T m a` arises, which does not allow to `unit`, `join` the `m` monadic layers.

* have desirable properies and can add them to monads. * user their implementation to solve the compostion type layering and allow to attach desirable property to result.

* solve monad composition and type layering by cheating, using own structure and information about itself. It is often that process involves a catamorphism of a * type layer.

In type signatures of transformers `*T m` - `m` is already an extended monad, so `*T` is just a wrapper to point that out.

Transformers have a light wrapper around the data that tags the modification with this transformer.

Main monadic structure `m` is wrapped around the internal data (core is `a`). The structure that corresponds to the transformer creation properties (if it emitted by η of a transformer), goes into `m` . Open parameters go external to the `m`.

```
newtype ExceptT e m a =
  ExceptT { runExceptT :: m (Either e a) }

newtype MaybeT m a =
  MaybeT { runMaybeT :: m (Maybe a) }

newtype ReaderT r m a =
  ReaderT { runReaderT :: r -> m a }
```

This has an effect that on stacking monad transformers, `m` becomes monad stack, and every next transformer injects the transformer creation-specific properies η inside the stack, so out-most transformer has inner-most structure. Base monad is structurally the outermost.

a. MaybeT * extends monads by injecting Maybe layer underneath monad, and processing that structure:

```
newtype MaybeT m a = MaybeT { runMaybeT :: m (Maybe a) }
```

b. EitherT * extends monads by injecting Either layer underneath monad, and processing that structure:

```
newtype EitherT e m a = EitherT { runEitherT [U+2237] m (Either e a) }
```

`EitherT` of `either` package gets replaced by `ExceptT` of `transformers` or `mtl` packages.

a. * ExceptT

c. ReaderT Definition:

```
newtype ReaderT r m a = ReaderT { runReaderT :: r -> m a }
```

* functions: input monad `m a`, out: `m a` wrapped it in a free-variable `r` (partially applied function).
That allows to use transformed `m a`, now it requires and can use the `r` passed environment.

To create a Reader monad:

```
type Reader r = ReaderT r Identity
```

d. MonadTrans type class Allows to lift monadic actions into a larger context in a neutral way.

`pure` takes a parametric type and embodies it into constructed structure (talking of monad transformers - structure of the stacked monads).

`lift` takes monad and extends it with a transformer.

In fact, for monad transformers - `lift` is a last stage of the `pure`, it follows from the lift law.

Method:

```
lift :: Monad m => m a -> t m a
```

Lift a computation from the argument monad to the constructed monad.

Neutral means:

```
lift . return = return

lift (m >>= f) = lift m >>= (lift . f)
```

The general pattern with MonadTrans instances is that it is usually lifts the injection of the known structure of transformer over some Monad.

lift embeds one monadic action into monad transformer.

The difference between pure, lift and MaybeT contructor becomes clearer if you look at the types:

Example, for `MaybeT IO a`:

```
pure      ::       a  -> MaybeT IO a
lift    ::     IO a  -> MaybeT IO a
MaybeT :: IO (Maybe a) -> MaybeT IO a

x = (undefined :: IO a)

:t (pure x)
(pure x) :: Applicative t => t (IO a)   -- t recieves one argument of product type
:t (pure x :: MaybeT IO a)
-- Expected type: MaybeT IO a1
--   Actual type: MaybeT IO (IO a0)

-- While the real type would be
:t (pure x :: MaybeT IO (IO a))
(pure x :: MaybeT IO (IO a)) :: MaybeT IO (IO a) -- This goes into a conflict of what ty

:t (lift x)
(lift x) :: MonadTrans t => t IO a   -- result is a proper expected product type

-- To belabour
```

```
:t (lift x :: MaybeT IO a)
(lift x) :: MonadTrans t => t IO a  -- result is a proper expected product type
```

`lift` is a natural transformation η from an Identity monad (functor) with other monad as content into transformer monad (functor), with the preservation of the conteined monad:

```
-- Abstract monads with content as parameters. Define '~>' as a family of morphisms that
type f ~> g = forall x. f x -> g x
-- follows
lift :: m ~> t m
```

a. MonadIO type class * - allows to lift IO action until reaching the IO monad layer at the top of the `Monad` stack (which is allways in the Haskell code that does IO).

```
class (Monad m) => MonadIO m where
  liftIO :: IO a -> m a
```

`liftIO` laws:

```
liftIO . pure = pure

liftIO (m >>= f) = liftIO m >>= (liftIO . f)
```

Which is identical laws to MonadTrans `lift`.

Since `lift` is one step, and liftIO all steps - all steps defined in terms of one step and all other steps, so the most frequent implementation is self-recursive `lift . liftIO`:

```
liftIO ioa = lift $ liftIO ioa
```

a. *

liftIO

3.5.7.7 Alternative type class

Monoid over applicative. Has left catch property.

Allows to run simolteniously several instances of a computation (or computations) and from them yeld one result by law from `(<|>) :: Type -> Type -> Type`.

Minimal complete definition:

```
empty :: f a     -- The identity element of <|>
(<|>) :: f a -> f a -> f a     -- Associative binary operation
```

a. *

Alternative

3.5.7.8 «<=*>=»>

Do calculation, but ignore the value from the first argument.

$* > \equiv >>$

3.5.8 Monoidal functor

Functors between monoidal categories that preserves monoidal structure.

3.5.9 Fusion

```
fmap f . fmap g = fmap (f . g)
```

* - functor axiom that allows to greatly simplify computations.

3.5.10 «<=$>=»>

Get & set a value inside Functor.

3.5.11 Multifunctor

Generalizes the concept of functor between categories, canonical morphisms between multicategories.

Works over N type arguments instead of one.

To put simply - accepts multiple argumets, from that informatioin constructs source product category (Cartesian product) of categories, and is a functor from product category to target category.

To put even simplier - functor that takes as an argument the product of types.

In Haskell there is only one category, Hask, so in Haskell * is still $(Hask \times Hask) \to Hask \Rightarrow |(Hask \times Hask) \equiv Hask| \Rightarrow Hask \to Hask$ endofunctor.

Any product or sum in a Cartesian category is a *.

Code definition:

```
class Bifunctor f
 where
  bimap :: (a -> a') -> (b -> b') -> f a a' -> f a a'
  bimap f g = first f . second g
  first :: (a -> a') -> f a b -> f a' b
  first f = bimap f id
  second :: (b -> b') -> f a b -> f a b'
  second = bimap id
```

3.5.11.1 *

Bifunctor

3.5.12 *

«<=<$=»>

3.6 Hask category

Category of Haskell where objects are types and morphisms are functions.

It is a hypothetical category at the moment, since undefined and bottom values break the theory, is not Cartesian closed, it does not have sums, products, or initial object, `()` is not a terminal object, monad identities fail for almost all instances of the Monad class.

That is why Haskell developers think in subset of Haskell where types do not have bottom values. This only includes functions that terminate, and typically only finite values. The corresponding category has the expected initial and terminal objects, sums and products, and instances of Functor and Monad really are endofunctors and monads.

Hask contains subcategories, like Lst containing only list types.

Haskell and Category concepts:

- Things that take a type and return another type are type constructors.
- Things that take a function and return another function are higher-order functions.

3.6.1 *

Hask

3.7 Magma

Set with a binary operation which form a closure.

3.7.1 Mag category

The category of magmas, denoted Mag, has as objects - sets with a binary operation, and morphisms given by homomorphisms of operations (in the universal algebra sense).

3.7.1.1 *

MAG
Magma category
Category of magmas

3.7.2 Semigroup

Magma with associative property of operation.

Defined in Haskell as:

```
class Semigroup a where
(<>) :: a -> a -> a
```

3.7.2.1 *

Semigroups

3.7.2.2 Monoid

Semigroup with identity element. Category with a one object.

Ideally fits as an accumulation class.

```
class Monoid m where
mempty :: m
mappend :: m -> m -> m
mappend = (<>)
mconcat :: [m] -> m
mconcat = foldr mappend mempty
```

* can be simplified to category with a single object, remember that monoid operation is a composition of morphisms operation in category.
For example to represent the whole non-negative integers with the one object and morphism "1" is absolutely enough, composition operation is "+".

```
import Data.Monoid
do
  show (mempty :: Num a => Sum a)
  -- "Sum {getSum = 0}"
  show $ Sum 1
  -- "Sum {getSum = 1}"
  show $ (Sum 1) <> (Sum 1) <> (Sum 1)
  -- "Sum {getSum = 3}"
  -- ...
```

Also backwards - any single-object category is a monoid. Category has an identity requirement and associativity of composition requirement, which makes it a free monoid.

a. *

Monoidal
Monoids

b. Monoid laws

a. Monoid left identity law

```
mempty <> x = x
```

b. Monoid right identity law

```
x <> mempty = x
```

c. Monoid associativity law

```
x <> mempty = x (y <> z) = (x <> y) <> z
mconcat = foldr (mempty <>)
```

Everything associative can be `mappend`.

c. Commutative monoid Commutativity property:
$x \circ y = y \circ x$

Opens a big abilities in concurrent and distributed processing.

  a. *
  Abelian monoid

d. Group Monoid that has inverse for every element.

  a. *
  Groups

  b. Commutative group Group operation obeys the axiom of commutativity.

    a. *
    Abelian group

    b. Ring Commutative group under $+$ & monoid under $\times$, $+$ $\times$ connected by distributive property.

      - and $\times$ are generalized binary operations of addition and multiplication. $\times$ has no requirement for commutativity.

    Example: set of same size square matricies of numbers with matrix operations form a ring.

      a. *
      Rings

3.8 Morphism

μορφ´ *morphe* form
Arrow between two objects in a category.

General description: Arrow from source to target. Denotes something.

On a level of objects: is probably structure-preserving map from one mathematical structure to another of the same type.

Morphism is a generalization ($f(x * y) \equiv f(x) \diamond f(y)$) of homomorphism ($f(x * y) \equiv f(x) * f(y)$). Under morphism almost always is the meaning of homomorphism-like properties.

Morphism can be anything.

If morphism corresponds to function requirements - then it is a function.

3.8.1 *

Morphisms
Arrow
Arrows

3.8.2 Homomorphism

$\mu\acute{}\varsigma$ *homos* same (was chosen becouse of initial Anglish mistranslation to "similar")
$\mu o\rho\varphi\acute{}$ *morphe* form
similar form

* map between two algebraic structures of the same type, operation-preserving.

$f_{x \to y} = f(a \star b) = f(a) \diamond f(b)$,
where x, y are sets with additonal algebraic structure that includes $\star, \diamond$ accordingly; a, b are elements of set x.

* sends identity morphisms to identity morphisms and inverses to inverses.

The concept of * has been generalized under the name of morphism to many structures that either do not have an underlying set, or are not algebraic.

3.8.2.1 *

Homomorphic

3.8.3 Identity morphism

Identity morphism - or simply identity: $x \in C : \ id_x = 1_x : x \to x$
Composed with other morphism gives same morphism.

Corresponds to Reflexivity and Automorphism.

3.8.3.1 Identity

Identity only possible with morphism. See Identity morphism.

There is also distinct Zero value.

a. Two-sided identity of a predicate $P(e, a) = P(a, e) = a \mid \exists e \in S, \forall a \in S$
   $P()$ is commutative.

   Predicate

b. Left identity of a predicate $\exists e \in S, \forall a \in S : \ P(e, a) = a$

   Predicate

c. Right identity of a predicate $P(a, e) = a \mid \exists e \in S, \forall a \in S$

Predicate

3.8.3.2 Identity function

Return itself.
(\ x.x)

```
id :: a -> a
```

3.8.4 Monomorphism

$\mu o \nu o$ *mono* only
$\mu o \rho \varphi \acute{}$ *morphe* form

Maps one to one (uniquely), so invertable (always has inverse morphism), so preserves the information/structure.
Domain can be equal or less to the codomain.

$f^{X \to Y}, \; \forall x \in X \, \exists! y = f(x) \vDash f(x) \equiv f_{mono}(x)$ - from homomorphism context
$f_{mono} \circ g1 = f_{mono} \circ g2 \; \vDash \; g1 \equiv g2$ - from general morphism context
Thus * is left canselable.

If * is a function - it is injective. Initial set of f is fully uniquely mapped onto the image of f.

3.8.4.1 *

Monomorphic
Monomorphisms

3.8.5 Epimorphism

$\varepsilon \pi \iota$ *epi* on, over
$\mu o \rho \varphi \acute{}$ *morphe* form

* is right canselable morphism.
$f^{X \to Y}, \forall y \in Y \, \exists f(x) \vDash f(x) \equiv f_{epi}(x)$ - from homomorphism context
$g_1 \circ f_{epi} = g_2 \circ f_{epi} \Rightarrow \; g_1 \equiv g_2$ - from general morphism context

In Set category if * is a function - it is surjective (image of it fully uses codomain)
Codomain is a called a projection of the domain.

* fully maps into the target.

3.8.5.1 *

Epimorphic
Epimorphisms

3.8.6 Isomorphism

$\sigma o\varsigma$ *isos* equal
$\mu o\rho\varphi\acute{}$ *morphe* form

Not equal, but equal for current intents and purposes.
Morphism that has inverse.
Almost equal, but not quite: `(Integer, Bool)` & `(Bool, Integer)` - but can be transformed losslessly into one another.

Bijective homomorphism is also isomorphism.

$f^{-1,b\to a} \circ f^{a\to b} \equiv 1^a, \; f^{a\to b} \circ f^{-1,b\to a} \equiv 1^b$

2 reasons for non-isomorphism:

- function at least ones collapses a values of domain into one value in codomain
- image (of a function in codomain) does not fill-in codomain. Then isomorphism can exists for image but not whole codomain.

Categories are isomorphic if there $R \circ L = ID$

3.8.6.1 *

Isomorphic
Isomorphisms

3.8.6.2 Lax

Holds up to isomorphism.
(upon the transformation can be used as the same)

3.8.7 Endomorphism

$\varepsilon\nu\delta o$ *endo* internal
$\mu o\rho\varphi\acute{}$ *morphe* form

Arrow from object to itself.
Endomorphism forms a monoid (object exists and category requirements already in place).

3.8.7.1 Automorphism

$\alpha\upsilon\tau o$ *auto* self
$\mu o\rho\varphi\acute{}$ *form* form

Isomorphic endomorphism.

Corresponds to identity, reflexivity, permutation.

a. *

Automorphic
Automorphisms

3.8.7.2 *

Endomorphic
Endomorphisms

3.8.8 Catamorphism

$\kappa\alpha\tau\acute{}$ *kata* downward
$\mu o\rho\varphi\acute{}$ *morphe* form

Unique arrow from an initial algebra structure into different algebra structure.

* in FP is a generalization folding, deconstruction of a data structure into more primitive data structure using a functor F-algebra structure.

* reduces the structure to a lower level structure.
* creates a projection of a structure to a lower level structure.

3.8.8.1 *

Catamorphic
Catamorphisms

3.8.8.2 Catamorphism law

Table 3.2: Catamorphism laws in Haskell

Rule name	Haskell
cata-cancel	`cata phi . InF = phi . fmap (cata phi)`
cata-refl	`cata InF = id`
cata-fusion	`f . phi = phi . fmap f => f . cata phi = cata phi`
cata-compose	`eps :: f :~> g => cata phi . cata (In . eps) = cata (phi . eps)`

a. Hylomorphism catamorphism ∘ anamorphism

Expanding and collapsing the structure.

a. *

Hylomorphic
Hylomorphisms

3.8.8.3 Anamorphism

Generalizes unfold.

Dual concept to catamorphism.

Increases the structure.

Morphism from a coalgebra to the final coalgebra for that endofunctor.

Is a function that generates a sequence by repeated application of the function to its previous result.

a. *

Anamorphic
Anamorphisms

3.8.9 Kernel

Kernel of a homomorphism is a number that measures the degree homomorphism fails to meet injectivity (AKA be monomorphic).
It is a number of domain elements that fail injectivity:

- elements not included into morphism
- elements that collapse into one element in codomain

thou Kernel $[x|x \leftarrow 0||x \geq 2]$.

Denotation:
$\ker T = \{\mathbf{v} \in V : T(\mathbf{v}) = \mathbf{0}_W\}$.

3.8.9.1 Kernel homomorphism

Morphism of elements from the kernel.
Complementary morphism of elements that make main morphism not monomorphic.

3.9 Set category

Category in which objects are sets, morphisms are functions.

Denotation:
Set

3.10 Natural transformation

Roughly * is:

```
trans :: F a -> G a
```

, while `a` is polymorphic variable.

Naturality condition: $\forall\ a\ \exists\ (F\ a \to G\ a)$, or , analogous to parametric polymorphism in functions. Since * in a category, stating $\forall(F\ a \to G\ a)$
Naturality condition means that all morphisms that take part in homotopy of source functor to target functor must exist, and that is the same, diagrams that take part in transformation, should commute, and different paths brins same result: if α - natural transformation, α_a natural transformation component - $G\ f \circ \alpha_a = \alpha_b \circ F\ f$.
Since * are just a type of parametric polymorphic function - they can compose.

* $(\overrightarrow{\eta}^{\mathcal{D}})$ is transforming : $\overrightarrow{\eta}^{\mathcal{D}} \circ F^{\mathcal{C}\to\mathcal{D}} = G^{\mathcal{C}\to\mathcal{D}}$.
* abstraction creates higher-language of Category theory, allowing to talk about the composition and transformation of complex entities.

It is a process of transforming $F^{\mathcal{C}\to\mathcal{D}}$ into $G^{\mathcal{C}\to\mathcal{D}}$ using existing morphisms in target category $\mathcal{D}$.

Since it uses morphisms - it is structure-preserving transformation of one functor into another. Iy mostly a lossy transformation. Only existing morphisms cab make it exist.

Existence of * between two functors can be seen as some relation.

Can be observed to be a "morphism of functors", especially in functor category.
* by $\overrightarrow{\eta}^{\mathcal{D}}_{y^{\mathcal{C}}}(\overrightarrow{(x,y)}^{\mathcal{C}}) \circ F^{\mathcal{C}\to\mathcal{D}}(\overrightarrow{(x,y)}^{\mathcal{C}}) = G^{\mathcal{C}\to\mathcal{D}}(\overrightarrow{(x,y)}^{\mathcal{C}}) \circ \overrightarrow{\eta}^{\mathcal{D}}_{x^{\mathcal{C}}}(\overrightarrow{(x,y)}^{\mathcal{C}})$, often written short $\overrightarrow{\eta}_b \circ F(\overrightarrow{f}) = G(\overrightarrow{f}) \circ \overrightarrow{\eta}_a$.
Notice that the $\overrightarrow{\eta}^{\mathcal{D}}_{x^{\mathcal{C}}}(\overrightarrow{(x,y)}^{\mathcal{C}})$ depends on objects&morphisms of $\mathcal{C}$.

In words: * depends on F and G functors, ability of D morphisms to do a homotopy of F to G, and *:

- for every object in $\mathcal{C}$ picks natural transformation component in $\mathcal{D}$.

- for every morphism in $\mathcal{C}$ picks the commuting diagram in $\mathcal{D}$, called naturality square.

Also see: Natural transformation in Haskell

Knowledge of * forms a 2-category.

Can be composed "vertically":

$$\begin{tikzcd}
a \arrow[r, bend left=50, "F"{name=F}] \arrow[r, "G"{name=G}] \arrow[r, bend right=50, "H"'{name=H}] & b
\arrow[Rightarrow, from=F, to=G, "\alpha"] \arrow[Rightarrow, from=G, to=H, "\beta"]
\end{tikzcd}$$

$$\begin{tikzcd}
a \arrow[r, bend left=50, "F"{name=F}] \arrow[r, bend right=50, "H"'{name=H}] & b
\arrow[Rightarrow, from=F, to=H, "\beta \circ \alpha"]
\end{tikzcd}$$

And horizontally, aka "Godement product":

$$\begin{tikzcd} a \arrow[r, bend left, "F_1"] \arrow[r, bend right, "G_1"'] \arrow[r, phantom, "\Downarrow\alpha"] & b \arrow[r, bend left, "F_2"] \arrow[r, bend right, "G_2"'] \arrow[r, phantom, "\Downarrow\beta"] & c \end{tikzcd}$$

$$\begin{tikzcd} a \arrow[r, bend left, "F_2 \circ F_1"] \arrow[r, bend right, "G_2 \circ G_1"'] \arrow[r, phantom, "\Downarrow\beta * \alpha"] & c \end{tikzcd}$$

Compositions can be done in any right order, they abide the exchange law.

3.10.1 *

Natural transformations
Naturality condition
Naturality

3.10.2 Natural transformation component

$\overrightarrow{\eta}^{\mathcal{D}}(x) = F^{\mathcal{D}}(x) \to G^{\mathcal{D}}(x) \mid x \in \mathcal{C}$

3.10.2.1 *

Component of natural transformation

3.10.3 Natural transformation in Haskell

Family of parametric polymorphism functions between endofunctors.

In Hask is $F\ a \to G\ a$. Can be analogued to repackaging data into another container, never modifies the object content, it only if - can delete it, because operation is lossy.

Can be sees as ortogonal to functors.

3.10.4 Cat category

Category where:

	Part	Is	#
*	object	category	0-cell
$\Rightarrow$	morphism	functor	1-cell
$\Rightarrow$	2-morphism	natural transformation, morphisms homotopy	2-cell

$$\begin{tikzcd} a \arrow[r, bend left, "F"] \arrow[r, bend right, "G"'] \arrow[r, phantom, "\Downarrow nt"] & b \end{tikzcd}$$

Is Cartesian closed category.

3.10.4.1 *

Cat
2-category

3.10.4.2 Bicategory

2-category that is enriched and lax.

For handling relaxed associativity - introduces associator, and for identity l -eft/right unitor.

Forming from bicategories higher categories by stacking levels of abstraction of such categories - leads to explosion of special cases, differences of every level, and so overall difficulties.

Stacking groupoids (category in which are morphisms are invertable) is much more homogenous up to infinity, and forms base of the homotopy type theory.

3.11 Category dual

Category duality behaves like a logical inverse.

Inverse $\mathcal{C} = \mathcal{C}^{op}$ - inverts the direction of morphisms.

Composition accordingly changes to the morphisms: $(g \circ f)^{op} = f^{op} \circ g^{op}$

Any statement in the terms of $\mathcal{C}$ in $\mathcal{C}^{op}$ has the dual - the logical inverse that is true in $\mathcal{C}^{op}$ terms.

Opposite preserves properties:

- products: $(\mathcal{C} \times \mathcal{D})^{op} \cong \mathcal{C}^{op} \times \mathcal{D}^{op}$
- functors: $(F^{\mathcal{C} \to \mathcal{D}})^{op} \cong F^{\mathcal{C}^{op} \to \mathcal{D}^{op}}$
- slices: $(\mathcal{F} \downarrow \mathcal{G})^{op} \cong (\mathcal{G}^{op} \downarrow \mathcal{F}^{op})$

a. *

Opposite category
Opposite categories
Category duality
Duality
Dual category
Dual

3.11.1 Coalgebra

Structures that are dual (in the category-theoretic sense of reversing arrows) to unital associative algebras.
Every coalgebra, by vector space duality, reversing arrows - gives rise to an algebra. In finite dimensions, this duality goes in both directions. In infinite - it should be determined.

3.12 Thin category

$\forall$ Hom sets contain zero or one morphism.

$f \equiv g \mid \forall x, y \; \forall f, g : x \to y$

A proset (preordered set).

3.12.1 *

Proset category
Prosetal category
Poset category
Posetal category

3.13 Commuting diagram

Establishes equality in morphisms that have same source and target.

Draws the morphisms that are:
$f = g \Rightarrow \{f, y\} : X \to Y$

3.13.1 *

Diagram commutes
Commutes

3.14 Universal construction

Algorythm of constructing definitions in Category theory.
Specially good to translate properties/definitions from other theories (Set theory) to Categories.

Method:

a. Define a pattern that you defining.

b. Establish ranking for pattern matches.

c. The top of ranking, the best match or set of matches - is the thing you was looking for. Matches are isomorphic for defined rules.

* uses Yoneda lemma, and as such constructions are defined until isomorphism, and so isomorphic betweem each-other.

3.14.1 *

Universal constructions

3.15 Product

Universal construction:

$$\begin{array}{ccccccc} & & & c' & & & \\ & {}^{p}\swarrow & & \downarrow ! & & \searrow^{q} & \\ a & \underset{\pi_a}{\leftarrow} & & c & & \underset{\pi_b}{\rightarrow} & b \end{array}$$

Pattern: $p : c \rightarrow a,\ q : c \rightarrow b$
Ranking: $\max \sum^{\forall} (! : c\prime \rightarrow c \mid p\prime = p\circ!,\ q\prime = q\circ!)$
$c\prime$ is another candidate.

For sets - Cartesian product.

* is a pair. Corresponds to product data type in Hask (inhabited with all elements of the Cartesian product).

Dual is Coproduct.

3.15.1 *

Products

3.16 Coproduct

Universal constructuon:

$$\begin{array}{ccccccc} & & & c\prime & & & \\ & {}^{p}\nearrow & & \uparrow ! & & \nwarrow^{q} & \\ a & \underset{\iota_a}{\rightarrow} & & c & & \underset{\iota_b}{\leftarrow} & b \end{array}$$

Pattern: $i : a \rightarrow c,\ j : b \rightarrow c$
Ranking: $\max \sum^{\forall} (! : c \rightarrow c\prime \mid i\prime =! \circ i,\ j\prime =! \circ j)$
$c\prime$ is another candidate.

For sets - Disjoint union.

* is a set assembled from other two sets, in Haskell it is a tagged set (analogous to disjoint union).

Dual is Product.

3.16.1 *

Coproducts

3.17 Free object

General particular structure.
In which structure, properties autofollows from definition, axioms.

Also uses as a term when surcomstances of structures, rules, properties, axioms used coinside with the definition of a particular object $\therefore$ form object of this type with the according properties and possibilities.

3.18 Internal category

Category which is includded into a bigger category.

3.19 Hom set

All morphisms from source object to target object.

Denotation:
$hom_C(X, Y) = (\forall f : X \to Y) = hom(X, Y) = C(X, Y)$
Denotation was not standartized.

Hom sets belong to Set category.

In Set category: $\exists!(a, b) \iff \exists!Hom, \forall Hom \in Set$. Set category is special, Hom sets are also objects of it.

Category can include Set, and hom sets, or not.

3.19.1 *

Hom-set
Hom sets

3.19.2 Hom-functor

$hom : \mathcal{C}^{op} \times \mathcal{C} \to Set$
Functor from the product of $\mathcal{C}$ with its opposite category to the category of sets.

Denotation variants:
$H_A = \mathrm{Hom}(-, A)$
$h_A = \mathcal{C}(-, A)$
$Hom(A, -) : \mathcal{C} \to Set$

Hom-bifunctor:
$Hom(-, -) : \mathcal{C}^{op} \times \mathcal{C} \to Set$

3.19.3 Exponential object

Generalises the notion of function set to internal object.
As also hom set to internal hom objects.

Cartesian closed (monoidal) category strictly required, as * multiplicaton holds composition requirement:

$\circ : hom(y, z) \otimes hom(x, y) \to hom(x, z)$

Denotation:
b^a

Universal construction:

$$\begin{tikzcd} c \arrow[d, dotted, "u"] & c \times a \arrow[d, dotted, "u\times 1^a"] \arrow[dr] & \\ b^a & b^a \times a \arrow[r, dotted, "eval"] & b \end{tikzcd}$$

, where in Category: b^a - exponential object, $\times$ - product bifunctor, a - argument of *, b - result, c - candidate, $b^a \equiv (a \Rightarrow b)$ - *.

* b^a (also as $(a \Rightarrow b)$) represent exponentiation of cardinality of $\forall b^a$ possiblities.

3.19.3.1 *

Function object
Internal hom
Exponential objects
Hom object
Hom objects

3.19.3.2 Enriched category

Uses Hom objects (exponential objects), which do not belong into Set category.
Category is no longer small, now may be called large.

$hom(x, y) \in K$.

Called: * over `K` (whick holds hom objects).

a. * Enriched
Large category

Chapter 4

Data type

Set of values.
For type to have sence the values must share some sence, properties.

4.1 *

Type
Types
Data types

4.2 Actual type

Data type recieved by ->inferring->compiling->execution.

4.3 Algebraic data type

Composite type formed by combining other types.

4.3.1 *

AlgDT

4.4 Cardinality

Number of possible implementations for a given type signature.

Disjunction, sum - adds cardinalities.
Conjunction, product - multiplies cardinalities.

4.4.1 *

Cardinalities

4.5 Data constant

* - constant value; nullary data constructor.

4.6 Data constructor

One instance that inhabit data type.

4.7 data declaration

Data type declaration is the most general and versatile form to create a new data type.
Form:

```
data [context =>] type typeVars1..n
  = con1  c1t1..i
  | ...
  | conm  cmt1..q
  [deriving]
```

4.8 Dependent type

When type and values have relation between them. Type has restrictions for values, value of a type variable has a result on the type.

4.8.1 *

Dependent types

4.9 Gen type

Generator. Gen type is to generate pseudo-random values for parent type. Produces a list of values that gets infinitely cycled.

4.10 Higher-kinded data type

Any combination of * and ->

Type that take more types as arguments.

Humbly really a function

4.10.1 *

Higher-kinded data types

4.11 newtype declaration

Create a new type from old type by attaching a new constructor, allowing type class instance declaration.

```
newtype FirstName = FirstName String
```

Data will have exactly the same representation at runtime, as the type that is wrapped.

```
newtype Book = Book (Int, Int)
```

```
      (,)
      / \
Integer Integer
```

4.12 Principal type

The most generic data type that still typechecks.

4.13 Product data type

Is an algebraic data type respesentation of a product construction.
Formed by logical conjunction (`AND`, '* *').

Haskell forms:

```
-- 1. As a tuple (the uncurried & most true-form)
(T1, T2)

-- 2. Curried form, data constructor that takes two types
C T1 T2

-- 3. Using record syntax. =r# <inhabitant>= would return the respective =T#=.
C { r1 :: T1
  , r2 :: T2
  }
```

4.13.1 *

Product type

4.13.2 Sequence

Enumerated (ordered) set.

Denotation:

```
()
( , )
( , , )
( , , ... )
```

More general mathematical denotation was not established, variants:
$(n)_{n\in\mathbb{N}}$
$\omega \to X$
$\{i : Ord \mid i < \alpha\}$

In Haskell: Data type that stores multiple ordered values withing a single value.

Table 4.1: Sequence constructor naming by arity

Name	Arity	Denotation
Unit, empty	0	()
Singleton	1	(_)
Tuple, pair, two-tuple	2	(,)
Triple, three-tuple	3	(, ,)
Sequence	N	(, , ...)

4.13.2.1 *

Sequences
Tuples
Ordered pair
Ordered triple

4.13.2.2 List

The same type objects sequence.

Denotation:

```
[]
[ , ]
[ , , ]
[ , , ... ]
```

Haskell definition:

```
data [] a = [] | a : [a]
```

Definition is self-referential (self-recursive), can be seen as anamorphism (unfold) of the `[]` (empty list, memory cell which is container of particular type) and `:` (cons operation, pointer). As such - can create non-terminating data type (and computation), in other words - infinite.

4.14 Proxy type

Proxy type holds no data, but has a phantom parameter of arbitrary type (or even kind). Able to provide type information, even though has no value of that type (or it can be may too costly to create one).

```
data Proxy a = ProxyValue

let proxy1 = (ProxyValue :: Proxy Int) -- a has kind `Type`
let proxy2 = (ProxyValue :: Proxy List) -- a has kind `Type -> Type`
```

4.15 Static typing

Typechecking takes place at compile level.

4.16 Structural type

Mathematical type. They form into structural type system.

4.16.1 *

Structural

4.17 Structural type system

Strict global hierarchy and relationships of types and their properties.
Haskell type system is *.
In most languages typing is name-based, not structural.

4.17.1 *

Structural typing

4.18 Sum data type

Algebraic data type formed by logical disjunction (OR '|').

4.19 Type alias

Create new type constructor, and use all data structure of the base type.

4.20 Type class

Type system construct that adds a support of ad hoc polymorphism.

Type class makes a nice way for defining behaviour, properties over many types/objects at once.

4.20.1 *

Type classes
Typeclass
Typeclasses

4.20.2 Arbitrary type class

Type class of QuickCheck.Arbitrary (that is reexported by QuickCheck) for creating a generator/distribution of values.
Useful function is arbitrary - that autogenerates values.

4.20.2.1 Arbitrary function

Depends on type and generates values of that type.

4.20.3 CoArbitrary type class

Pseudogenerates a function basing on resulting type.

```
coarbitrary :: CoArbitrary a => a -> Gen b -> Gen b
```

4.20.3.1 *

CoArbitrary

4.20.4 Typeable type class

Allows dynamic type checking in Haskell for a type.
Shift a typechecking of type from compile time to runtime.
* type gets wrapped in the universal type, that shifts the type checks to runtime.

Also allows:

- Get the type of something at runtime (ex. print the type of something `typeOf`).
- Compare the types.
- Reifying functions from polymorphic type to conrete (for functions like `:: Typeable a => a -> String`).

4.20.4.1 *

Typeable

4.20.5 Type class inheritance

Type class has a superclass.

4.20.6 Derived instance

Type class instances sometimes can be automatically derived from the parent types.

Type classes such as Eq, Enum, Ord, Show can have instances generated based on definition of data type.

P.S.

Language options:

- DeriveAnyClass
- DeriveDataTypeable
- DeriveFoldable
- DeriveFunctor
- DeriveGeneric
- DeriveLift
- DeriveTraversable
- DerivingStrategies
- DerivingVia
- GeneralisedNewtypeDeriving
- StandaloneDeriving

4.20.6.1 *

Derived
Deriving

4.21 Type constant

Nullary type constructor.

4.22 Type constructor

Name of the data type.

Constructor that takes type as an argument and produces new type.

4.23 type declaration

Synonim for existing type. Uses the same data constructor.

```
type FirstName = String
```

Used to distinct one entities from other entities, while they have the same type.
Also main type functions can operate on a new type.

4.24 Typed hole

*** - is a `_` or `_name` in the expression. On evaluation GHC would show the derived type information which should be in place of the ***. That information helps to fill in the gap.

4.24.1 *

Typed holes

4.25 Type inference

Automatic data type detection for expression.

4.25.1 *

Inferring
Infer
Infers
Inferred

4.26 Type class instance

Block of implementations of functions, based on unique type class->type pairing.

4.27 Type rank

Weak ordering of types.

The rank of polymorphic type shows at what level of nesting `forall` quantifier appears.
Count-in only quantifiers that appear to the left of arrows.

```
f1 :: forall a b. a -> b -> a    ==    fi :: a -> b -> c
g1 :: forall a b. (Ord a, Eq b) => a -> b -> a    ==    g1 :: (Ord a, Eq b) => a -> b -> a
```

f1, g1 - rank-1 types. Haskell itself implicitly adds universal quantification.

```
f2 :: (forall a. a->a) -> Int -> Int
g2 :: (forall a. Eq a => [a] -> a -> Bool) -> Int -> Int
```

f2, g2 - rank-2 types. Quantificator is on the left side of a →. Quantificator shows that type on the left can be overloaded.

Type inference in Rank-2 is possible, but not higher.

```
f3 :: ((forall a. a->a) -> Int) -> Bool -> Bool
```

f3 - rannk3-type. Has rank-2 types on the left of a →.

```
f :: Int -> (forall a. a -> a)
g :: Int -> Ord a => a -> a
```

f, g are rank 1. Quantifier appears to the right of an arrow, not to the left. These types are not Haskell-98. They are supported in RankNTypes.

4.27.1 *

Type ranks
Rank type
Rank types
Rank-1 type
Rank-1 types
Rank-2 type
Rank-2 types
Rank-3 type
Rank-3 types

4.28 Type variable

Refer to an unspecified type in Haskell type signature.

4.29 Unlifted type

Type that directly exist on the hardware. The type abstraction can be completely removed. With unlifted types Haskel type system directly manages data in the hardware.

4.29.1 *

Unlifted types

4.30 Data structure

4.30.1 Cons cell

Cell that values may inhabit.

4.30.2 Construct

```
(:) :: a -> [a] -> [a]
```

4.30.2.1 *

Cons

4.30.3 Leaf

```
-
```

4.30.4 Node

```
 *
/ \
```

4.31 Linear type

Type system and algebra that also track the multiplicity of data.
There are 3 general linear type groups:

- 0 - exists only at type level and is not allowed to be used at value level. Aka `s` in ST-Trick.
- 1 - data that is not duplicated
- 1< - all other data, that can be duplicated multiple times.

4.31.1 *

Linear types

4.32 NonEmpty list data type

Data.List.NonEmpty
Has a Semigroup instance but can't have a Monoid instance. It never can be an empty list.

```
data NonEmpty a = a :| [a]
  deriving (Eq, Ord, Show)
```

:| - an infix data costructor that takes two (type) arguments. In other words :| returns a product type of left and right

4.33 Session type

* - allows to check that behaviour conforms to the protocol.

So far very complex, not very productive (or well-established) topic.

4.34 Binary tree

```
data BinaryTree a
  = [[Leaf]]
  | [[Node]] (BinaryTree a) a (BinaryTree a)
```

4.35 Bottom value

A _ non-value in the type or pattern match expression. Placeholder for enything.

```
-- _ fits *.
```

4.35.1 *

Bottom
Bottom values

4.36 Bound

Haskell * type class means to have lowest value & highest value, so a bounded range of values.

4.36.1 *

Bounded

4.37 Constructor

a. Type constructor

b. Data constructor

Also see: Constant

4.37.1 *

Constructors

4.38 Context

Type constraints for polymorphic variables.
Written before the main type signature, denoted:

```
TypeClass a => ...
```

4.38.1 *

Contexts

4.39 Inhabit

Values that is a component of data type set.

4.40 Maybe

```
data Maybe
  = Nothing
  | Just a
```

Does not represent the information why `Nothing` happened.
For error - use Either.
Do not propagate *.

Handle * locally to where it is produced. `Nothing` does not hold useful info for debugging & short-circuits the processes. Do not expect code type being bug-free, do not return `Maybe` to end user since it would be impossible to debug, return something that preserves error information.

4.40.0.1 *

Nodes

4.41 Expected type

Data type inferred from the text of the code.

4.42 ADT

a. Abstract data type

b. Algebraic data type

4.43 Concrete type

Fully defined type. Non-polymorphic type.

4.44 Type punning

When type constructor and data constructor have the same name.

Theoretically if person knows the rules - * can be solved, because in Haskell type and data declaration have different places of use.

4.45 Kind

Kind -> Type -> Data

4.45.1 *

Kinds

4.46 IO

Type for values whose evaluations has a posibility to cause side effects or return unpredictable result.
Haskell standard uses monad for constructing and transforming IO actions.
IO action can be evaluated multiple times.

IO data type has unpure imperative actions inside. Haskell is pure Lambda calculus, and unpure IO integrates in the Haskell purely (type system abstracts IO unpurity inside IO data type).

IO sequences effect computation one after another in order of needed computation, or occurence:

```haskell
twoBinds :: IO ()
twoBinds =
  putStrLn "First:" >>
  getLine >>=
  \a ->
  putStrLn "Second:" >>
  getLine >>=
  \b ->
  putStrLn ("\nFirst: "
    ++ a ++ ".\nSecond "
    ++ b ++ ".")
main = twoBinds
```

Sequencing is achieved by compilation of effects performing only while they recieve the sugared-in & passed around the `RealWorld` fake type value, that value in the every computation gets the new "value" and then passed to the next requestes computation. But special thing is about this parameter, this `RealWorld` type value passed, but never looked at. GHC realizes, since value is never used, - it means value and type can be equated to `()` and moreover reduced from the code, and sequencing stays.

Chapter 5

Declaration

Binding name to expression.

Chapter 6

Differential operator

Denotation.
$\frac{d}{dx}$, D, D_x, ∂_x.
Last one is partial.

$e^{t\frac{d}{dx}}$ - Shift operator.

6.1 *

Differential

Chapter 7

Dispatch

Send, transmission, reference.

Chapter 8

Effect

Observable action.

Chapter 9

Evaluation

For FP see Bind.

Chapter 10

Expression

Finite combination of symbols that is well-formed according to rules that depend on the context.

10.1 *

Expressions

10.2 Closed-form expression

* - mathematical expression that can be evaluated in a finite number of operations.

May contain:

- constants
- variables
- operations (e.g., $+ - \times \div$)
- functions (e.g., nth root, exponent, logarithm, trigonometric functions, and inverse hyperbolic functions), but usually no limit.

10.3 RHS

Right-hand side of the expression.

10.4 LHS

Left-hand side of the expression.

10.5 Redex

Reducible expression.

10.6 Concatenate

Link together sequences, expressions.

10.7 Alpha equivalence

Equivalence of a processes in expressions. If expressions have according parameters different, but the internal processes are literally the same process.

10.8 Ground expression

Expression that does not contain any free variables.

10.8.1 *

Ground formula

10.9 Variable

A name for expression.

Haskell has immutable variables.
Except when you hack it with explicit funtions.

10.9.1 *

Variables

Chapter 11

First-class

Means *it*:

- Can be used as value.

- Passed as an argument.

From 1&2 -> *it* can include itself.

Chapter 12

Function

Full dependency of one quantity from another quantity.

Denotation:
$y = f(x)$
$f : X \to Y$,
where X is domain, Y is codomain.

Directionality and property of invariability emerge from one another.

```
-- domain func codomain
   *        ->    *
```

$y(x) = (zx^2 + bx + 3 \mid b = 5)$
^ ^ ^^ ^ ^

\Var \Constant
\Bound variable
\Free variable
\Parameter

\Name of the function

Lambda abstraction is a function.
Function is a mathematical operation.

Function = Total function = Pure function. Function theoretically can be to memoized.

Also see:
Partial function
Inverse function - often partially exists (partial function).

12.1 *

Functions
Bound variable

12.2 Arity

Number of parameters of the function.

- nullary - f()
- unary - f(x)
- binary - f(x,y)
- ternary - f(x,y,z)
- n-ary - f(x,y,z..)

12.3 Bijection

Function is a complete one-to-one pairing of elements of domain and codomain (image).
It means function both surjective (so image == codomain) and injective (every domain element has unique correspondence to the image element).

For bijection inverse always exists.

Bijective operation holds the equivalence of domain and codomain.

Denotation:

```
[U+2916]
>->>
f : X [U+2916] Y
```

LaTeX needed to combine symbols:
$f : X \rightarrowtail\!\!\!\!\twoheadrightarrow Y$

Corersponds to isomorphism.

12.3.1 *

Bijective
Bijective function

12.4 Combinator

Function without free variables.
Higher-order function that uses only function application and other combinators.

```
\a -> a
\ a b -> a b
\f g x -> f (g x)
\f g x y -> f (g x y)
```

Not combinators:

```
\ xs -> sum xs
```

Informal broad meaning: referring to the style of organizing libraries centered around the idea of combining things.

12.5 Function application

* - bind the argument to the parameter of a function, and do a beta-reduction.

12.5.1 *

Apply
Applied
Applying
Application

12.6 Function body

Expression that haracterizes the process.

12.7 Function composition

```
(.) :: (b -> c) -> (a -> b) -> a -> c
```

```
a -> (a -> b) -> (b -> c) -> c
```

In Haskell inline composition requires:

```
h.g.f $ i
```

12.7.1 *

Composition
Compose
Composed

12.8 Function head

Is a part with name of the function and it's paramenters.
AKA: $f(x)$

12.9 Function range

The range of a function refers to either the codomain or the image of the function, depending upon usage. Modern usage almost always uses range to mean image.
So, see Function image.

12.10 Higher-order function

Function arity > 1.

—-

Has function as a parameter.
Evaluates to function.

12.10.1 *

HOF

12.10.2 Fold

Catamorphism of a structure to a lower type of structure. Often to a single value.

* is a higher-order function that takes a function which operates with both main structure and accumulator structure, * applies units of data structure to a function wich works with accumulator. Upoun traversing the whole structure - the accumulator is returned.

12.11 Injection

Function one-to-one injects from domain into codomain.

Keeps distinct pairing of elements of domain and image.
Every element in image coresponds to one element in domain.

$\forall a, b \in X,\ f(a) = f(b) \Rightarrow a = b$

$\exists(inverse\ function) \mid \forall(injective\ function)$

Denotion:

```
↣
>->
f : X ↣ Y
```

$f : X \rightarrowtail Y$

Corresponds to Monomorphism.

12.11.1 *

Injective
Injective function
Injectivity

12.12 Partial function

One that does not cover all domain.
Unsafe and causes trouble.

12.13 Purity

* means properly abstracted.

If the contrary - abstraction is unpure.

Also see: pure function.

12.13.1 *

Pure

12.14 Pure function

Function that is pure $\equiv$ referentially transparent function.

12.15 Sectioning

Writing function in a parentheses. Allows to pass around partially applied functions.

12.16 Surjection

Function uses codomain fully.

$\forall y \in Y, \exists x \in X$

Denotation:
$f : X \twoheadrightarrow Y$

Corresponds to Epimorphism.

12.16.1 *

Surjective
Surjective function

12.17 Unsafe function

Function that does not cover at least one edge case.

12.17.1 *

Unsafe

12.18 Variadic

* - having variable arity (often up to indefinite).

12.19 Domain

Source set of a function.
X in $X \to Y$.

12.20 Codomain

Y in $X \to Y$.
Codomain - target set of a function.

12.21 Open formula

Logical function that has arity and produces proposition.

12.22 Recursion

Repeated function application when sometimes same function gets called.

Allows computation that may require indefinite amount of work.

12.22.1 *

Recursive

12.22.2 Base case

A part of a recursive function that trivially produces result.

12.22.3 Tail recursion

Tail calls are recursive invocantions of itself.

12.22.4 Polymorphic recursion

Type of the parameter changes in recursive invocations of function.

Is always a higher-ranked type.

12.22.4.1 *

Milner–Mycroft typability
Milner–Mycroft calculus

12.23 Free variable

Variable in the fuction that is not bound by the head.
Until there are * - function stays partially applied.

12.24 Closure

$f(x) = f^{\mathcal{X} \to \mathcal{X}} \mid \forall x \in \mathcal{X}$, $\mathcal{X}$ is closed under f, it is a trivial case when operation is legitimate for all values of the domain.

Operation on members of the domain always produces a members of the domain. The domain is closed under the operation.

In the case when there is a domain values for which operation is not legitimate/not exists:

$f(x) = f^{\mathcal{V} \to \mathcal{X}} \mid \mathcal{V} \in \mathcal{X}, \forall x \in \mathcal{V}$, $\mathcal{X}$ is closed under f.

12.24.1 *

Closed

12.25 Parameter

$\pi\alpha\rho\acute{}$ *para* subsidiary
$\mu\acute{}\tau\rho o\nu$ *metron* measure

Named varible of a function.

Argument is a supplied value to a function parameter.

Parameter (formal parameter) is an irrefutable pattern, and implemeted that way in Haskell.

12.25.1 *

Parameters
Formal parameter
Formal parameters

12.26 Partial application

Part of function parameters applied.

12.26.1 *

Partially applied

12.27 Well-formed formula

Expression, logical function that is/can produce a proposition.

12.27.1 *

Well formed formula
WFF
wff
WFFS
wffs

Chapter 13

Homotopy

$\mu\acute{}\varsigma$ homós same

One can be "continuously deformed" into the other.

For example - functions, functors.
Natural transformation is a homotopy of functors.

13.1 *

Homotopies
Homotopic

Chapter 14

Lambda calculus

Universal model of computation. Which means * can implement any Turing machine.
Based on function abstraction and application by substituting variables and binding values.

* has lambda terms:

- variable (x)
- application ((ts))
- abstraction (lambda function) ($(\lambda x.t)$)

14.1 *

Lambda term
Lambda terms
Lambda variable
Lambda variables

14.2 Lambda cube

λ-cube shows the 3 dimentions of generalizations from simply typed Lambda calculus to Calculus of constructions.

Each dimension of the cube corresponds to a new way of making objects depend on other objects:

- (First-class polymorphism) - terms allowed to depend on types, corresponding to polymorphism.
- (Higher-rank polymorphism) - types depending on terms, corresponding to dependent types.
- (Type class) - types depending on types, corresponding to type operators.

14.2.1 *

λ-cube
λ-cube

14.3 Lambda function

Function of Lambda calculus.
$\lambda xy.x^2 + y^3$
^^ ^ ^

\variable
\variable
(_)
_BODY

\parameter

_ parameter
(_)
_ _HEAD

14.3.1 *

Lambda abstraction

14.3.2 Anonymous lambda function

Lambda function that is not binded to any name.

14.3.2.1 *

Anonymous lambda function

14.4 β-reduction

Equation of a parameter to a bound variable, then reducing parameter from the head.

14.4.1 *

β reduction
Beta-reduction
Beta reduction

14.4.2 β-normal form

No beta reduction is possible.

14.4.2.1 *

β normal from
Beta normal form
Beta-normal form

14.5 Calculus of constructions

Extends the Curry–Howard correspondence to the proofs in the full intuitionistic predicate calculus (includes proofs of quantified statements).
Type theory, typed programming language, and constructivism (phylosophy) foundation for mathematics.
Directly relates to Coq programming language.

14.5.1 *

«<CoC»>

14.6 Curry–Howard correspondence

Equivalence of {First-order logic, computer programming, Category theory}. They represent each-other, possible in one - possible in the other, so all the definitions and theorems have analogues in other two.

Gives a ground to the equivalence of computer programs and mathematical proofs.

Lambek added analogue to Cartesian closed category, which can be used to model logic and type theory.

Table 14.1: Table of basic correspondence

Logic	Type	Category
True	() (any inhabited type)	Terminal
False	Void	Initial
$a \wedge b$	(a, b)	$a \times b$
$a \vee b$	Either a b	a / b
$a \Rightarrow b$	$a \to b$	b^a

14.6.1 *

Curry–Howard isomorphism
Curry-Howard-Lambek

14.7 Currying

Translating the evaluation of a multiple argument function (or a tuple of arguments) into evaluating a sequence of functions, each with a single argument.

14.7.1 *

Curry

14.8 Hindley–Milner type system

Classical type system for the Lambda calculus with Parametric polymorphism and Type inference. Types marked as polymorphic variables, which enables type inference over the code.

14.8.1 *

Hindley-Milner
Damas-Milner
Damas–Hindley–Milner

14.9 Reduction

Take out something from a structure, make simplier.

See Beta reduction

14.9.1 *

Reducible

14.10 β-η normal form

All β-reduction and η-abstraction are done in the expression.

14.10.1 *

beta-eta normal form
beta eta normal form

14.11 η-abstraction

$(\lambda x.Mx) \underset{\eta}{\leftarrow} M$

```
\ x -> g . f $ x
\ x -> g . f      --eta-abstraction
```

14.11.1 *

14.12 Lambda expression

See Lambda calculus (Lambda terms) and Expression. In majority cases meaning some Lambda function.

Chapter 15

Lense

Library of combinators to provide Haskell (functional language without mutation) with the emulation of `get`-ters and `set`-ters of imperative language.

Chapter 16

Operation

Calculation into output value. Can have zero & more inputs.

16.1 Constant

Nullary operation.

Also see: Type constant.

16.2 Binary operation

$\forall(a, b) \in S, \exists P(a, b) = f(a, b) : S \times S \to S$

16.2.1 *

Binary operations

16.3 Operator

Denotation symbol/name for the operation.

16.3.1 Shift operator

Shift operator defined by Lagrange through Differential operator.
$T^t = e^{t\frac{d}{dx}}$

16.3.1.1 *

Shift

16.4 Infix

Form of writing of operator or function in-between variables for application.

For priorities see Fixity.

16.5 Fixity

Declares the presedence of action of a function/operator.

Funciton application has presedence higher then all infix operators/functions (virtually giving it a priority 10).

Table 16.1: Haskell operators priority and fixity association

P	L	Non	R
10			F.A.
9	!!		.
8			^ ^^ **
7	*/ div		
6	+-		
5			: , ++
4		<comparison> elem	
3			&&
2			OR
1			
0			$ $! seq

Infixl
Infixr
Priority
Precedence

16.6 Zero

* is the value with which operation always yelds Zero value.
$zero, n \in C : \forall n, zero * n = zero$

* is distinct from Identity value.

Chapter 17

Permutation

Bijective function from domain to itself.

Domain & permutation functions & function composition form a group.

Chapter 18

Phrase

Composable expression.

Chapter 19

Point-free

Paradigm where function only describes the morphism itself.

Process of converting function to point-free.
If brackets *()* can be changed to *$* then $ equal to composition:

```
\ x -> g (f x)
\ x -> g $ f x
\ x -> g . f $ x
\ x -> g . f      --eta-abstraction

\ x1 x2 -> g (f x1 x2)
\ x1 x2 -> g $ f x1 x2
\ x1 x2 -> g . f x1 $ x2
\ x1    -> g . f x1
```

19.1 *

Pointfree
Tacit
Tacit programming

19.2 Blackbird

```
(.).(.) :: (b -> c) -> (a1 -> a2 -> b) -> a1 -> a2 -> c
```

Composition of compositions `(.).(.)`. Allows to compose-in a binary function `f1(c) (.).(.) f2(a,b)`.

```
\ f g x y -> f (g x y)
```

19.2.1 *

.) .
(.).(.)
Composition of compositions

19.3 Swing

```
swing :: (((a -> b) -> b) -> c -> d) -> c -> a -> d
swing = flip . (. flip id)
swing f = flip (f . runCont . return)
swing f c a = f ($ a) c
```

19.4 Squish

```
f >>= a . b . c =<< g
```

Chapter 20

Polymorphism

πολ´ς polús many

At once several forms.

In Haskell - abstract over data types.

* types:

20.1 *

Polymorphic

20.2 Levity polymorphism

Extending polymorphism to work with unlifted and lifted types.

20.3 Parametric polymorphism

Abstracting over data types by parameter.

In most languages named as 'Generics' (generic programming).

Types:

20.3.1 Rank-1 polymorphism

Parametric polymorphism in rank-1 types by type variables.

20.3.1.1 *

Prenex
Prenex polymorpism

20.3.2 Let-bound polymorphism

It is property chosen for Haskell type system.
Haskell is based on Hindley-Milner type system, it is let-bound.
To have strict type inference with * - if `let` and `where` declarations are polymorphic - λ declarations - should be not.

See: Good: In Haskell parameters bound by lambda declaration instantiate to only one concrete type.

20.3.3 Constrained polymorphism

Constrained Parametric polymorphism.

20.3.3.1 Ad hoc polymorphism

Artificial constrained polymorphism dependent on incoming data type.
It is interface dispatch mechanism of data types.
Achieved by creating a type class instance functions.

Commonly known as overloading.

a. *

Ad-hoc polymorphism
Ad hoc polymorphic
Ad-hoc polymorphic
Constraint
Constraints

20.3.4 Impredicative polymorphism

* allows type τ entities with polymorphic types that can contain type τ itself.
$T = \forall X.X \to X : T \in X \vDash T \in T$

The most powerful form of parametric polymorphism.
See: Impredicative.

This approach has Girard's paradox (type systems Russell's paradox).

20.3.4.1 *

First-class polymorphism

20.3.5 Higher-rank polymorphism

Means that polymorphic types can apper within other types (types of function).
There is a cases where higher-rank polymorphism than the a Ad hoc - is needed. For example where ad hoc polymorphism is used in constraints of several different implementations of functions, and you want to build a function on top - and use the abstract interface over these functions.

```
-- ad-hoc polymorphism
f1 :: forall a. MyType Class a => a -> String    ==    f1 :: MyType Class a => a  -> String
f1 = -- ...

-- higher-rank polymorphism
f2 :: Int -> (forall a. MyType Class a => a -> String) -> Int
f2 = -- ...
```

By moving `forall` inside the function - we can achive higher-rank polymorphism.

From: `https://news.ycombinator.com/item?id=8130861`

```
Higher-rank polymorphism is formalized using System F, and there are a few implementations of (in
```

Useful example aslo a ST-Trick monad.

20.3.5.1 *

Rank-n polymorphism

20.4 Subtype polymorphism

Allows to declare usage of a Type and all of its Subtypes.
T - Type
S - Subtype of Type
$<:$ - subtype of
$S <: T = S \leq T$

Subtyping is:
If it can be done to T, and there is subtype S - then it also can be done to S.
$S <: T : \ f^{T \to X} \Rightarrow f^{S \to X}$

20.5 Row polymorphism

Is a lot like Subtype polymorphism, but alings itself on allowence (with | r) of subtypes and types with requested properties.

```
printX :: { x :: Int | r } -> String
printX rec = show rec.x

printY :: { y :: Int | r } -> String
printY rec = show rec.y

-- type is inferred as `{x :: Int, y :: Int | r } -> String`
printBoth rec = printX rec ++ printY rec
```

20.6 Kind polymorphism

Achieved using a phantom type argument in the data type declaration.

```
;;          * -> *
data Proxy a = ProxyValue
```

Then, by default the data type can be inhabited and fully work being partially defined.
But multiple instances of kind polymorphic type can be distinguished by their particular type.

Example is the Proxy type:

```
data Proxy a = ProxyValue

let proxy1 = (ProxyValue :: Proxy Int) -- * :: Proxy Int
let proxy2 = (ProxyValue :: Proxy a)   -- * -> * :: Proxy a
```

20.7 Linearity polymorphism

Leverages linear types.
For exampe - if fold over a dynamic array:

a. In basic Haskell - array would be copied at every step.

b. Use low-level unsafe functions.

c. With Linear type function we guarantee that the array would be used only at one place at a time.

So, if we use a function (* -o * -o -o *) in foldr - the fold will use the initial value only once.

Chapter 21

Pragma

Pragma - instruction to the compiler that specifies how a compiler should process the code.
Pragma in Haskell have form:

```
{-# PRAGMA options #-}
```

21.1 LANGUAGE pragma

Controls what variations of the language are permitted.
It has a set of allowed options: https://downloads.haskell.org/~ghc/latest/docs/html/users_guide/glasgow_exts.html, which can be supplied.

21.1.1 LANGUAGE option

21.1.1.1 *

Language options

21.1.1.2 Useful by default

```
import EmptyCase
import FlexibleContexts
import FlexibleInstances
import InstanceSigs
import MultiParamTypeClasses
```

21.1.1.3 AllowAmbiguousTypes

Allow type signatures which appear that they would result in an unusable binding.
However GHC will still check and complain about a functions that can never be called.

21.1.1.4 ApplicativeDo

Enables an alternative in-depth reduction that translates the do-notation to the operators `<$>`, `<*>`, `join` as far as possible.

For GHC to pickup the patterns, the final statement must match one of these patterns exactly:

```
pure E
pure $ E
return E
return $ E
```

When the statements of do expression have dependencies between them, and ApplicativeDo cannot infer an Applicative type - GHC uses a heuristic $O(n^2)$ algorithm to try to use <*> as much as possible. This algorithm usually finds the best solution, but in rare complex cases it might miss an opportunity. There is aslo $O(n^3)$ algorithm that finds the optimal solution: `-foptimal-applicative-do`.

Requires `ap = <*>`, `return = pure`, which is true for the most monadic types.

- Allows use of do-notation with types that are an instance of Applicative and Functor

- In some monads, using the applicative operators is more efficient than monadic bind. For example, it may enable more parallelism.

The only way it shows up at the source level is that you can have a `do` expression with only Applicative or Functor constaint.

It is possible to see the actual translation by using `-ddump-ds`.

21.1.1.5 ConstrainedClassMethods

Enable the definition of further constraints on individual class methods.

21.1.1.6 CPP

Enable C preprocessor.

21.1.1.7 DeriveFunctor

Automatic deriving of instances for the Functor type class.
For type power set functor is unique, its derivation inplementation can be autochecked.

21.1.1.8 ExplicitForAll

Allow explicit forall quantificator in places where it is implicit by Haskell.

21.1.1.9 FlexibleContexts

Ability to use complex constraints in class declaration contexts.
The only restriction on the context in a class declaration is that the class hierarchy must be acyclic.

```
class C a where
  op :: D b => a -> b -> b

class C a => D a where ...
```

$C :> D$, so in C we can talk about D.

Synergizes with ConstraintKinds.

21.1.1.10 FlexibleInstances

Allow type class instances types contain nested types.

```
instance C (Maybe Int) where ...
```

Implies TypeSynonymInstances.

21.1.1.11 GeneralizedNewtypeDeriving

Enable GHC's `newtype` cunning generalised deriving mechanism.

```
newtype Dollars = Dollars Int
  deriving (Eq, Ord, Show, Read, Enum, Num, Real, Bounded, Integral)
```

(In old Haskell-98 only Eq, Ord, Enum could been inherited.)

21.1.1.12 ImplicitParams

Allow definition of functions expecting implicit parameters. In the Haskell that has static scoping of variables allows the dynamic scoping, such as in classic Lisp or ELisp.
Sure thing this one can be puzzling as hell inside Haskell.

21.1.1.13 LambdaCase

Enables expressions of the form:

```
\case { p1 -> e1; ...; pN -> eN }

-- OR

\case
  p1 -> e1
  ...
  pN -> eN
```

21.1.1.14 MultiParamTypeClasses

Implies: ConstrainedClassMethods
Enable the definitions of typeclasses with more than one parameter.

```
class Collection c a where
```

21.1.1.15 MultiWayIf

Enable multi-way-if syntax.

```
if | guard1 -> code1
   | ...
   | guardN -> codeN
```

21.1.1.16 OverloadedStrings

Enable overloaded string literals (string literals become desugared via the `IsString` class).

With overload, string literals has type:

```
(IsString a) => a
```

The usual string syntax can be used, e.g. `ByteString`, `Text`, and other variations of string-like types.
Now they can be used in pattern matches as `char->integer` translations. To pattern match `Eq` must be derived.

To use class `IsString` - import it from `GHC.Ext`.

21.1.1.17 PartialTypeSignatures

Partial type signature containins wildcards, placeholders (`_`, `_name`).
Allows programmer to which parts of a type to annotate and which to infer. Also applies to constraint part.

As untuped expression, partly typed can not polymorphicly recurse.

-Wno-partial-type-signatures supresses infer warnings.

21.1.1.18 RankNTypes

Enable types of arbitrary rank.
See Type rank.

Implies ExplicitForAll.

Allows `forall` quantifier:

- Left side of →
- Right side of →
- as argument of a constructor
- as type of a field

- as type of an implicit parameter
- used in pattern type signature of lexically scoped type variables

21.1.1.19 ScopedTypeVariables

By default type variables do not have a scope except inside type signatures where they are used.

When there are internall type signatures provided in the code block (`where`, `let`, etc.) they (main type description of a function and internal type descriptions) restrain one-another and become not trully polymorphic, which creates a bounding interdependency of types that GHC would complain about.

* option provides the lexical scope inside the code block for type variables that have forall quantifier. Because they are now lexiacally scoped - those type variables are used across internal type signatures.

For details see: https://ocharles.org.uk/guest-posts/2014-12-20-scoped-type-variables.html

Implies ExplicitForAll.

21.1.1.20 TupleSections

Allow tuple section syntax:

```
(, True)
(, "I", , , "Love", , 1337)
```

21.1.1.21 TypeApplications

Allow type application syntax:

```
read @Int 5

:type pure @[]
pure @[] :: a -> [a]

:type (<*>) @[]
(<*>) @[] :: [a -> b] -> [a] -> [b]

--

instance (CoArbitrary a, Arbitrary b) => Arbitrary (a -> b)

λ> ($ 0) <$> generate (arbitrary @(Int -> Int))
```

21.1.1.22 TypeSynonymInstances

Now type synonim can have it's own type class instances.

21.1.1.23 UndecidableInstances

Permit instances which may lead to type-checker non-termination.

GHC has Instance termination rules regardless of FlexibleInstances FlexibleContexts.

21.1.1.24 ViewPatterns

```
foo (f1 -> Pattern1) = c1
foo (fn -> Pattern2 a b) = g1 a b
```

(*expression* → *pattern*): take what is came to match - apply the *expression*, then do *pattern*-match, and return what originally came to match.

Semantics:

- *expression* & *pattern* share the scope, so also variables.

n (*expression* → *pattern*) t1.

* are like pattern guards that can be nested inside of other patterns.
* are a convenient way to pattern-match algebraic data type.

Additional possible usage:

```
foo a (f2 a -> Pattern3 b c) = g2 b c  -- only for function definitions
foo ((f,_), f -> Pattern4) = c2  -- variables can be bount to the left in data constructors and t
```

21.1.1.25 DatatypeContexts

Allow contexts in data types.

```
data Eq a => Set a = NilSet | ConsSet a (Set a)

-- NilSet :: Set a
-- ConsSet :: Eq a => a -> Set a -> Set a
```

Considered misfeature. Deprecated. Going to be removed.

21.1.1.26 StandaloneKindSignatures

Type signatures for type-level declarations.

```
type <name_1> , ... , <name_n> :: <kind>

type MonoTagged :: Type -> Type -> Type
data MonoTagged t x = MonoTagged x

type Id :: forall k. k -> k
type family Id x where
  Id x = x
```

```
type C :: (k -> Type) -> k -> Constraint
class C a b where
  f :: a b

type TypeRep :: forall k. k -> Type
data TypeRep a where
  TyInt   :: TypeRep Int
  TyMaybe :: TypeRep Maybe
  TyApp   :: TypeRep a -> TypeRep b -> TypeRep (a b)
```

< GHC 8.10.1 - type signatures were only for term level declarations.

Extension makes signatures feature more uniformal.

Allows to set the order of quantification, order of variables in a kind. For example when using TypeApplications.

Allows to set full kind of derivable class, solving situations with GADT return kind.

a. *

SAKS
Standalone kind signatures

21.1.1.27 PartialTypeSignatures

Very healpful. Helps to solve type level, helps to establish type signatures and constraints. Allow to provide _ in the type signatures to automatically infere-in the type information there.

Wild cards:

- Type

```
f :: _ -> _ -> a
```

- Constraint

```
f :: _ => a -> b -> c
```

- Named

```
f :: _x -> _x -> a
```

allows to identify the same wildcard.

21.1.2 How to make a GHC LANGUAGE extension

In `libraries/ghc-boot-th/GHC/LanguageExtensions/Type.hs` add new constructor to the `Extension` type

```
data Extension
  = Cpp
  | OverlappingInstances
  ...
  | Foo
```

/main/DynFlags.hs extend xFlagsDeps:

```
xFlagsDeps = [
  flagSpec "AllowAmbiguousTypes" LangExt.AllowAmbiguousTypes,
  ...
  flagSpec "Foo"                 LangExt.Foo
]
```

It is for basic case. For testing, parser see further: https://blog.shaynefletcher.org/2019/02/adding-ghc-language-extension.html

Chapter 22

Predicative

Non-self-referencing definition.

—

Antonym - *Impredicative.*

Chapter 23

Compositionality

Complex expression is determined by the constituent expressions and the rules used to combine them.

If the meaning fully obtainable form the parts and composition - it is full, pure compositionality.

If there exists composed idiomatic expression - it is unfull, unpure compositionality, because meaning leaks-in from the sources that are not in the composition.

23.1 *

Principe of compositionality
Composition
Compositional

Chapter 24

Ψ-combinator

Transforms two of the same type, applying same mediate transformation, and then transforming those into the result.

```
import Data.Function (on)
on :: (b -> b -> c) -> (a -> b) -> a -> a -> c
```

```
--\
   * ---
--/
```

24.1 *

Psi-combinator
On-combinator

Chapter 25

Quantifier

Specifies the quantity of specimens.

Two most common quantifiers ∀ (Forall) and ∃ (Exists).
∃! - one and only one (exists only unique).

25.1 *

Quantification
Quantifiers
Quantified

25.2 Forall quantifier

Permits to not infer the type, but to use any that fits. The variant depends on the LANGUAGE option used:
ScopedTypeVariables
RankNTypes
ExistentialQuantification

25.2.1 *

Forall

Chapter 26

Referential transparency

Given the same input return the same output.
So:
* expression can be replaced with its corresponding resulting value without change for program's behavior.
* functions are pure.

26.1 *

Referentially transparent

Chapter 27

Relation

Relationship between two objects.
Subset of a Cartesian product between sets of objects.
Is not directed and not limited.

27.1 *

Relations
Relationship

Chapter 28

REPL

Read-eval-print loop, aka interactive shell.

Chapter 29

Semantics

Philosophical study of meaning.
Meaning of symbols, words.

29.1 Operational semantics

Constructing proofs from logical assertions and verifying/checking/asserting things about execution and procedures their properties, such as correctness, safety or security.

Good to solve in-point localized tasks.

Process of abstraction.

29.2 Denotational semantics

Construction of objects, that describe/tag the meanings. In Haskell often abstractions that are ment (denotations), implemented directly in the code, sometimes exist over the code - allowing to reason and implement.

* are composable.

Good to achive more broad approach/meaning.

Also see Abstraction.

29.2.1 Abstraction

abs away from, off (in absentia)
tractus draw, haul, drag

Purified generalization of process.

Forgeting the details (axiomatic semantics). Simplified approach. Out of sight - out of mind.

* creates a new semantic level in which one can be absolutely precise (operational semantics).

It is a great did to name an abstraction (denotational semantics).

29.2.1.1 *

Abstractions
Abstracting
Abstract

29.2.1.2 Leaky abstraction

Abstraction that leaks details that it is supposed to abstract away.

a. *

Leaky abstractions

29.2.1.3 Object

Absolute abstraction.

Point.

Can have properties.

Often abstracts sometging, for example some structure, maybe mathematical.

a. *

Structure
Structures
Objects

b. Terminal object One that recieves unique arrow from every object.

$\exists ! : x \to 1 \mid \exists 1 \in \mathcal{C}, \ \forall x \in \mathcal{C}$

* is an empty sequence `()` in Haskell.

Called a *unit*, so recieves *terminal* or *unit* arrow.

Dual of initial object.

Denotation:

Category theory
1

Haskell

```
()
```

c. Initial object One that emits unique arrow into every object.

$\exists ! : \varnothing \to x \mid \exists \varnothing \in \mathcal{C}, \ \forall x \mathcal{C}$

If initial object is `Void` (most frequently) - emitted arrows called absurd, because they can not be called.

Dual of terminal object.

Denotation:

Category theory:
$\varnothing$

Haskell:

```
Void
```

29.2.2 Ambigram

ambi both
$\gamma\rho\acute{}\mu\mu\alpha$ *grámma* written character

Object that from different points of view has the same meaning.

While this word has two contradictory diametrically opposite usages, one was chosen (more frequent).

But it has... Both.

TODO: For merit of differentiating the meaning about different meaning referring to Tensor as object with many meanings.

29.2.3 Binary

Two of something.

29.2.4 Arbitrary

arbitrarius uncertain

Random, any one of.

Used as: Any one with *this* set of properties. (constraints, type, etc.).

When there is a talk about any arbitrary value - in fact it is a talk about the generalization of computations over the set of properties.

29.2.5 Refutable

One that has an option to fail.

29.2.6 Irrefutable

One that can not fail.

29.3 Axiomatic semantics

Empirical process of studying something complex by finding and analyzing true statements about it.

Good for examining interconnections.

29.3.1 Property

Something has a property in the real world, and in theory its property corresponds to the law/laws, axioms.

In Haskell under property/law most often properties of algebraic structures.

There property testing wich does what it says.

29.3.1.1 *

Properties

29.3.1.2 Associativity

Joined with common purpose.

$P(a, P(b, c)) \equiv P(P(a, b), c) \mid \forall (a, b, c) \in S,$

* - the operations can be grouped arbitrarily.

Property that determines how operators of the same precedence are grouped, (in computer science also in the absence of parentheses).

Etymology:
Latin *associatus* past participle of *associare* "*join with*", from assimilated form of *ad* "*to*" + *sociare* "*unite with*", from *socius* "*companion, ally*" from PIE **sokw-yo-*, suffixed form of root **sekw-* "*to follow*".

In Haskell * has influence on parsing when compounds have same fixity.

a. *

Associative
Associative law

Associativity law

29.3.1.3 Left associative

* - the operations are grouped from the left.

Example:
In lambda expressions same level parts follow grouping from left to right.
$(\lambda x.x)(\lambda y.y)z \equiv ((\lambda x.x)(\lambda y.y))z$

a. *

Left associativity
Left-associative

29.3.1.4 Right associative

* - the operations are grouped from the right.

29.3.1.5 Non-associative

Operations can't be chained.

Often is the case when the output type is incompatible with the input type.

29.3.1.6 Basis

$\beta\alpha\sigma\iota\varsigma$ - stepping

The initial point, unreducible axioms and terms that spawn a theory.
AKA see Category theory, or Euclidian geometry basis.

a. Contravariant The property of basis, in which if new basis is a linear combination of the prior basis, and the change of basis inverse-proportional for the description of a Tensors in this basisis.

   Denotation:
   Components for contravariant basis denoted in the upper indices:
   $V^i = x$

   The inverse of a covariant transformation is a contravariant transformation. Whenever a vector should be invariant under a change of basis, that is to say it should represent the same geometrical or physical object having the same magnitude and direction as before, its components must transform according to the contravariant rule.

   a. *

      Contravariant cofunctor
      Contravariant functor - More inline term is Contravariant cofunctor

b. Covariant The property of basis, in which if new basis is a linear combination of the prior basis, and the change of basis proportional for a descriptions of tensors in basisis.

Denotation:
Components for covariant basis denoted in the upper indices:
$V_i = x$

a. *
Covariant functor
Covariant cofunctor

29.3.1.7 Commutativity

$\forall(a, b) \in S : \; P(a, b) \equiv P(b, a)$

a. *
Commutative
Commutative law

29.3.1.8 Idempotence

First application gives a result. Then same operation can be applied multiple times without changing the result.
Example: Start and Stop buttons on machines.

a. *
Idempotent
Idempotency

29.3.1.9 Distributive property

Set S and two binary operators $+$ $\times$:

- $x \times (y + z) = (x \times y) + (x \times z)$ - $\times$ is left-distributive over $+$
- $(y + z) \times x = (y \times x) + (z \times x)$ - $\times$ is right-distributive over $+$
- left-&right-distributive - $\times$ is distributive over $+$

a. *
Distributive rule
Distributive axiom
Distributive law
Distributive

29.4 Argument

arguere to make clear, to shine

* - evidence, proof, statement that results in system consequences.

29.4.1 Argument of a function

A value binded to the function parameter. Value/topic that the fuction would process/deal with.

Also see Argument.

29.4.1.1 *

Function argument

29.5 Content word

Words that name objects of reality and their qualities.

29.6 Ancient Greek and Latin prefixes

29.6.1 *

Greek prefix
Latin prefix

29.7 Idiom

* - something having a meaning that can not be derived from the conjoined meanings. Meaning can be special for language speakers or human with particular knowledge.

* can also mean applicative functor.

29.7.1 *

Idioms
Idiomatic

29.8 Impredicative

Self-referencing definition.

—

Antonym - *Predicative*.

Table 29.1: Ancient Greek and Latin prefixes

29.9 Context-free grammar

Type of formal grammar that is: a set of production rules that describe all possible string is a given formal language.

Term is invented by Noam Chomsky.

29.9.1 *

CFG

Chapter 30

Set

Well-defined collection of distinct objects.

30.1 *

Sets
Set theory

30.2 Closed set

a. Set which complements an open set.

b. Is form of Closed-form expression. Set can be closed in under a set of operations.

30.3 Power set

For some set $\mathcal{S}$, the power set ($\mathcal{P}(\mathcal{S})$) is a set of all subsets of $\mathcal{S}$, including $\{\}$ & $\mathcal{S}$ itself.

Denotation:
$\mathcal{P}(\mathcal{S})$

30.4 Singleton

Singleton - unit set - set with exactly one element.
Also 1-sequence.

30.5 Russell's paradox

If there exists normal set of all sets - it should contain itself, which makes it abnormal.

30.6 Cartesian product

$\mathcal{A} \times \mathcal{B} \equiv \sum^{\forall} (a, b) \mid \forall a \in \mathcal{A}, \forall b \in \mathcal{B}$.
Operation, returns a set of all ordered pairs (a, b)

Any function, functor is a subset of Cartesian product.

$\sum (elem \in (\mathcal{A} \times \mathcal{B})) = cardinality^{A \times B}$

Properties:

- not associative
- not commutative

30.6.1 Pullback

Subset of the cartesian product of two sets.

30.6.1.1 *

Pullbacks

Chapter 31

Shrinking

Process of reducing coplexity in the test case - re-run with smaller values and make sure that the test still fails.

Chapter 32

Spine

Is a chain of memory cells, each points to the both value of element and to the next memory cell.

```
Array:

   :
  / \
 1   :
    / \
   2   :
      / \
     3  []

1:2:3:[]

Spine:
   :
  / \
 _   :
    / \
   _   :
      / \
     _  []
```

Chapter 33

Superclass

Broader parent class.

Chapter 34

Tensor

Object existing out of planes, thus it can translate objects from one plane into another.
They can be tried to be described with knowledge existing inside planes, but representation would always be partial.
Tensor of rank 1 is a vector.

Translatioin with tensor can be seen as functors.

34.1 *

Tensors
Tensorial

Chapter 35

Testing

35.1 Property testing

Since property has a law, then family of that unit tests can be abstracted into the lambda function.
And tests cases come from generator.

35.1.1 Function property

Property corresponds to the according law.
In property testing you need to think additionally about generator and shrinking.

35.1.2 Property testing type

Table 35.1: Property testing types

	Exhaustive	Randomized	Unit test
Whole set of values	Exhaustive property test	Randomised property test	One eleme
Special subset of values	Exhaustive specialised property test	Randomised specialised property test	One elem

35.1.3 Generator

```
Seed
|
v
Gen A -> A
^
|
Size
```

Seed allows reproducibility.
There is anyway a need to have some seed.
Size allows setting upper bound on size of generated value. Think about infinity of list.

After failed test - shrinking tests value parts of contrexample, finds a part that still fails, and recurses shrinking.

35.1.3.1 *

Generators

35.1.3.2 Custom generator

When sertain theorem only works for a specific set of values - the according generator needs to be produced.

```
arbitrary :: Arbitrary a => Gen a
suchThat :: Gen a -> (a -> Bool) -> Gen a
elements :: [a] -> Gen a
```

35.1.4 Reusing test code

Often it is convinient to abstract testing of same function properties:

It can be done with (aka TestSuite combinator):

```
-- Definition
{-# LANGUAGE ScopedTypeVariables #-}
{-# LANGUAGE AllowAmbiguousTypes #-}
eqSpec :: forall a. Arbitrary a => Spec

-- Usage
{-# LANGUAGE TypeApplications #-}
spec :: Spec
spec = do
  eqSpec @Int

Eq Int
  (==) :: Int -> Int -> Bool
    is reflexive
    is symetric
    is transitive
    is equivalent to (\ a b -> not $ a /= b)
  (/=) :: Int -> Int -> Bool
    is antireflexive
    is equivalent to (\ a b -> not $ a == b)
```

35.1.4.1 Test Commutative property

Commutativity

```
:: Arbitrary a => (a -> a -> a) -> Property
```

35.1.4.2 Test Symmetry property

Symmetry

```
:: Arbitrary a => (a -> a -> Bool) -> Property
```

35.1.4.3 Test Equivalence property

Equivalence

```
:: (Arbitrary a, Eq b) => (a -> b) -> (a -> b) -> Property
```

35.1.4.4 Test Inverse property

```
:: (Arbitrary a, Eq b) => (a -> b) -> (b -> a) -> Property
```

35.1.5 QuickCheck

`Target` is a member of the Arbitrary type class.
`Target -> Bool` is something `Testable`. This properties can be complex.
Generator `arbitrary` gets the seed, and produces values of `Target`.
Function `quickCheck` runs the loop and tests that generated `Target` values always comply the property.

35.1.5.1 Manual automation with QuickCheck properties

```
import Test.QuickCheck
import Test.QuickCheck.Function
import Test.QuickCheck.Property.Common
import Test.QuickCheck.Property.Functor
import Test.QuickCheck.Property.Common.Internal

data Four' a b = Four' a a a b
  deriving (Eq, Show)

instance Functor (Four' a) where
  fmap f (Four' a b c d) = Four' a b c (f d)

instance (Arbitrary a, Arbitrary b) ⇒ Arbitrary (Four' a b) where
  arbitrary = do
    a1 ← arbitrary
    a2 ← arbitrary
    a3 ← arbitrary
    b ← arbitrary
    return (Four' a1 a2 a3 b)

-- Wrapper around `prop_FunctorId`
prop_AutoFunctorId [U+2237] Functor f ⇒ f a → Equal (f a)
prop_AutoFunctorId = prop_FunctorId T

type Prop_AutoFunctorId f a
  = f a
  → Equal (f a)

-- Wrapper around `prop_AutoFunctorCompose`
prop_AutoFunctorCompose [U+2237] Functor f ⇒ Fun a1 a2 → Fun a2 c → f a1 → Equal (f c)
prop_AutoFunctorCompose f1 f2 = prop_FunctorCompose (applyFun f1) (applyFun f2) T

type Prop_AutoFunctorCompose structureType origType midType resultType
  = Fun origType midType
  → Fun midType resultType
```

```
→ structureType origType
→ Equal (structureType resultType)

main = do
  quickCheck $ eq $ (prop_AutoFunctorId [U+2237] Prop_AutoFunctorId (Four' ())Integer)
  quickCheck $ eq $ (prop_AutoFunctorId [U+2237] Prop_AutoFunctorId (Four' ()) (Either Bool Strin
  quickCheck $ eq $ (prop_AutoFunctorCompose [U+2237] Prop_AutoFunctorCompose (Four' ()) String I
  quickCheck $ eq $ (prop_AutoFunctorCompose [U+2237] Prop_AutoFunctorCompose (Four' ()) Integer
```

35.2 Write tests algorithm

a. Pick the right language/stack to implement features.

b. How expensive breakage can be.

c. Pick the right tools to test this.

Chapter 36

Uncurry

Replace sequenced lambda functions into single function taking sequence/product of values as argument.

Chapter 37

Unit

Represents existence. Denoted as empty sequence.

`()`

Type `()` holds only self-representation constructor `()`, & constructor holds nothing.

Haskell code always should recieve something back, hense nothing, emptiness, void can not be theoretically addressed, practically constructed or recieved - unit in Haskell also has a role of a stub in place of emptiness, like in `IO ()`.

Chapter 38

Nullary

Takes no entries; has the arity of zero.
Has the trivial domain.

Chapter 39

Logic

39.1 Proposition

Purely abtract & theoretical logical object (idea) that has a Boolean value.

* is expressed by a statement.

39.1.1 *

Propositions

39.1.2 Atomic proposition

Logically undividable unit. Does not contain logical connectives.

39.1.2.1 *

Atomic propositions

39.1.3 Compound proposition

Formed by connecting propositions by logical connectives.

39.1.3.1 *

Compound propositions

39.1.4 Propositional logic

Studies propositions and argument flow.

Refers to logically indivisible units (atomic propositions) as such, for theory - they are abstractions with Boolean properties.

Not Turing-complete, impossible to construct an arbitrary loop.

39.1.4.1 *

Proposition logic
Proposition calculus
Propositional calculus
Statement logic
Sentential logic
Sentential calculus
Zeroth-order logic

39.1.4.2 First-order logic

Notation systems that use quantifiers, relations, variables over non-logical objects, allows the use of expressions that contain variables.

Turing-complete.

Extension of a propositional logic.

a. *

Predicate logic
First-order predicate logic
First-order predicate calculus

b. Second-order logic Extension over first-order logic that quantifies over relations.

a. Higher-order logic Extension over second-order logic that uses additional quantifiers, stronger semantics.

Is more expressive, but model-theoretic properties are less well-behaved.

39.2 Logical connective

Logical operation.

39.2.1 *

Logical connectives

39.2.2 Conjunction

Logical AND.

Denotation:
$\wedge$

Multiplies cardinalities.

Haskell kind:

* *

39.2.3 Disjunction

Logical OR
Denotation:
$\vee$

Summs cardinalities.

39.3 Predicate

Function with Boolean codomain.
$P : X \to \{true,\ false\}$ - * on X.

Notation: $P(x)$

Almost always can include relations, quantifiers.

39.4 Statement

Declarative expression that is a bearer of a proposition.

When we talk about expression or statement being true/false - in fact we refer to the proposition that they represent.

Difference between proposition, statement, expression:

a. "$2 + 3 = 5$"

b. "two plus three equals five"

- 1 & 2 are statements. Each of them is a collection of transmission symbols (linguistic objects) from a symbol systems $\equiv$ expression. Each of them is expression that bears proposition (an idea resulting in a Boolean value) $\equiv$ statement.
- 1 & 2 represent the same proposition. Proposition from 1 $\equiv$ proposition from 2.
- Statement 1 $\neq$ statement 2. They are two different statements, written in different systems. And statement "$2 + 3 = 5$" $\neq$ statement "$3 + 2 = 5$".

39.4.1 *

Assertion
Assertions
Statements

39.5 Iff

If and only if, exectly when, just.
Denotation:
$\iff$

Chapter 40

Haskell structures

40.1 Pattern match

Are not first-class. It is a set of patter match semantic notations.

Must be linear.

* precedence (especially with more then one parameter, especially with _ used) often changes the function.

40.1.1 As-pattern

```
f list@(x, xs) = ...

f (x:xs)   = x:x:xs -- Can be compiled with reconstruction of x:xs
f a@(x:_) = x:a -- Reuses structure without reconstruction
```

40.1.1.1 *

As-patterns
As pattern
As patterns

40.1.2 Wild-card

Matches anything and can not be binded. For matching someting that should pass not checked and is not used.

```
head (x:_)             = x
tail (_:xs)            = xs
```

40.1.2.1 *

Wild-cards
Wildcard
Wildcards

40.1.3 Case

```
case x of
  pattern1  -> ex1
  pattern2  -> ex2
  pattern3  -> ex3
  otherwise -> exDefault
```

Bolting guards & expressions with syntatic sugar on case:

```
case () of _
  | expr1     -> ex1
  | expr2     -> ex2
  | expr3     -> ex3
  | otherwise -> exDefault
```

Pattern matching in function definitions is realized with case expressions.

40.1.4 Guard

Check values against the predicate and use the first match definition:

```
f x
  | predicate1 = definition1
  | predicate2 = definition2
  ...
  | x < 0      = definitionN
  ...
  | otherwise  = definitionZ
```

40.1.4.1 *

Guards

40.1.5 Pattern guard

Allows check a list of pattern matches against functions, and then proceed.

$$(patternMatch1) <\text{-} (funcCheck1)$$

, $(patternMatch2)$ <- $(funcCheck2)$
= *RHS*

```
lookup :: Eq a => a -> [(a, b)] -> Maybe b

addLookup l a1 a2
   | Just b1 <- lookup a1 l
   , Just b2 <- lookup a2 l
   = b1 + b2
{-...other equations...-}
```

Run functions, they must succeed. Then pattern match results to `b1`, `b2`. Only if successful - execute the equation.

Default in Haskell 2010.

40.1.5.1 *

Pattern guards

40.1.6 Lazy pattern

Defers the pattern match directly to the last moment of need during execution of the code.

```
f (a, b) = g a b -- It would be checked that the pattern of the pair constructor
-- is present, and that parameters are present in the constructor.
-- Only after that success - work would start on the RHS, aka then construction
-- g would start only then.

f ~(a, b) = g a b -- Pattern match of (a, b) deferred to the last moment,
-- RHS starts, construction of g starts.
-- For this lazy pattern the  equivalent implementation would be:
-- f p = g (fst p) (snd p)  -- RHS starts, during construction of g
-- the arguments would be computed and found, or error would be thrown.
```

Due to full laziness deferring everything to the runtime execution - the lazy pattern is one-size-fits all (irrefutable), analogous to `_`, and so it does not produce any checks during compilation, and raises errors during runtime.

* is very useful during recursive construction of recursive structure/process, especially infinite.

40.1.6.1 *

Lazy-pattern
Lazy patterns

40.1.7 Pattern binding

Entire LHS is a pattern, is a lazy pattern.

```
fib@(1:tfib)    = 1 : 1 : [ a+b | (a,b) <- zip fib tfib ]
```

40.1.7.1 *

Pattern bindings

40.2 Smart constructor

Process/code placing extra rules & constraints on the construction of values.

40.3 Level of code

There are these levels of Haskell code:

40.3.1 *

Code level

40.3.2 Type level

Level of code that works with data types.

40.3.2.1 Type level declaration

```
type ...
newtype ...
data ...
class ...
instance ...
```

a. *

Type level declarations
Type-level declaration
Type-level declarations

40.3.2.2 Type check

`if` The type level information is complete (strongly connected graph)

`then`

Generalize the types and check if type level consistent to term level.

`else`

Infer the missing type level part from the term level. There are certain situations and structures where ambiguity arises and is unsolvable from the information of the term level (most basic example is polymorphic recursion).

a. *

Typecheck
Typechecking
Typechecks

b. Complete user-specific kind signature Type level declaration is considered to "have a CUSK" is it has enough syntatic information to warrant completeness (strongly connected graph) and start checking type level correspondence to term level, it is a ad-hock state ot type inferring.

In the future GHC would use other algorythm over/instead of CUSK.

a. *
   CUSK
   CUSKs
   Complete user-specific kind signatures
   Complete, user-specific kind signature

40.3.3 Term level

Level of code that does logical execution.

40.3.4 Compile level

Level of code, about compilation processes/results.

40.3.4.1 *

Compilation level

40.3.5 Runtime level

Level of code of main program operation, when machine does computations with compiled binary code.

40.3.6 Kind level

Level of code where kinds & kind declarations are situated, infered and checked.

40.3.6.1 Kind check

Applying the type check to kind check:

`if` The kind level information is complete (strongly connected graph)

`then`

Check if kind level consistent to term level.

`else`

Infer the missing kind level parts from the type level. There are certain situations and structures where ambiguity arises and is unsolvable from the information of the kind level.

With `StandaloneKindSignatures` kind completeness happens against found (standalone) kind signature.

With `CUSKs` extension kind completeness happens agains "complete user-specific kind signature"

a. *

   Kindcheck
   Kind checks

40.4 Orphan type instance

Hanging type instance from inconsistent code base.

a. Supporting structure not fully present.

b. Several implementations of instance present.

40.5 Undefined

Placeholder value that helps to do typechecking.

40.6 Hierarchical module name

Hierarchical naming scheme:

```
Algebra                 -- Was this ever used?
    DomainConstructor   -- formerly DoCon
    Geometric           -- formerly BasGeomAlg

Codec                   -- Coders/Decoders for various data formats
    Audio
       Wav
       MP3
       ...
    Compression
       Gzip
       Bzip2
       ...
    Encryption
       DES
       RSA
       BlowFish
       ...
    Image
       GIF
       PNG
       JPEG
       TIFF
       ...
    Text
       UTF8
       UTF16
       ISO8859
```

```
      ...
    Video
      Mpeg
      QuickTime
      Avi
      ...
    Binary                 -- these are for encoding binary data into text
      Base64
      Yenc

Control
    Applicative
    Arrow
    Exception           -- (opt, inc. error & undefined)
    Concurrent          -- as hslibs/concurrent
        Chan            -- these could all be moved under Data
        MVar
        Merge
        QSem
        QSemN
        SampleVar
        Semaphore
    Parallel            -- as hslibs/concurrent/Parallel
        Strategies
    Monad               -- Haskell 98 Monad library
        ST              -- ST defaults to Strict variant?
            Strict      -- renaming for ST
            Lazy        -- renaming for LazyST
        State           -- defaults to Lazy
            Strict
            Lazy
        Error
        Identity
        Monoid
        Reader
        Writer
        Cont
        Fix              -- to be renamed to Rec?
        List
        RWS

Data
    Binary              -- Binary I/O
    Bits
    Bool                -- &&, ||, not, otherwise
    Tuple               -- fst, snd
    Char                -- H98
    Complex             -- H98
    Dynamic
    Either
    Int
    Maybe               -- H98
    List                -- H98
    PackedString
    Ratio               -- H98
```

```
    Word
    IORef
    STRef                 -- Same as Data.STRef.Strict
        Strict
        Lazy              -- The lazy version (for Control.Monad.ST.Lazy)
    Binary                -- Haskell binary I/O
    Digest
        MD5
        ...               -- others (CRC ?)
    Array                 -- Haskell 98 Array library
        Unboxed
        IArray
        MArray
        IO                -- mutable arrays in the IO/ST monads
        ST
    Trees
        AVL
        RedBlack
        BTree
    Queue
        Bankers
        FIFO
    Collection
    Graph                 -- start with GHC's DiGraph?
    FiniteMap
    Set
    Memo                  -- (opt)
    Unique

    Edison                -- (opt, uses multi-param type classes)
        Prelude           -- large self-contained packages should have
        Collection        -- their own hierarchy?  Like a vendor branch.
        Queue             -- Or should the whole Edison tree be placed

Database
    MySQL
    PostgreSQL
    ODBC

40.6.1 *

Top-level module name
Top-level module names

40.7 import

`import` statement by default imports identifiers from the other module, using hierarchical module name, brings into scope the identifiers to the global scope both into unqualified and qualifies by the hierarchical module name forms.

This possibilities can mix and match:

- `<modName> ()` - import only instances of type classes.
- `<modName> (x, y)` - import only declared indentifiers.
- `qualified <modName>` - discards unqialified names, forse obligatory namespace for the imports.

- `hiding (x, y)` - skip import of declared identifies.
- `<modName> as <modName>` - renames module namespace.
- `<type/class> (..)` - import class & it's methods, or type, all its data constructors & field names.

40.8 Let

* expression is a set of cross-recursive lazy pattern bindings.

Declarations permitted:

- type signatures
- function bindings
- pattern bindings

It is an expression (macro) and that integrates in external lexical scope expression it applied in.

Form:

```
let
  b1
  bn
in
  c
```

40.8.1 *

Let expression
Let expressions

40.9 Where

Part of the syntax of the whole function declaration, has according scope.

As part of whole declaration - can extend over definitions of the funtion (pattern matches, guards).

Form:

```
f match1 = y
f match2 = y
f x =
  | cond1 x = y
```

```
  | cond2 x = y
  | otherwise = y
 where
  y = ... x ...
```

40.9.1 *

Where clause

40.10 Reserved word

Haskell has special meaning for:

`case, class, data, deriving, do,else, if, import, in, infix, infixl,infixr, instance, let, of, mo`

40.10.1 *

Reserved words

40.11 Haskell Language Report

Chapter 41

Computer science

41.1 Guerrilla patch

* changing code/applying patch sneakily - and possibility incompatibility with other at runtime. Monkey patch is derivative term.

41.1.1 Monkey patch

From Guerrilla patch.

* is a way for program to modify supporting system software affecting only the running instance of the program.

41.2 Interface

Point of mutual meeting. Code behind interface determines how data is consumed.

41.3 Module

Importable organizational unit.

41.4 Scope

Area where binds are accessible.

41.4.1 Dynamic scope

The name resolution depends upon the program state when the name is encountered, which is determined by the execution context or calling context.

41.4.2 Lexical scope

Scope bound by the structure of source code where the named entity is defined.

41.4.2.1 *

Static scope

41.4.3 Local scope

Scope applies only in (current) area.

41.4.3.1 *

Local

41.5 Shadowing

When in the local scope bigger scope variable overriden by same name variable from the local scope.

41.6 Syntatic sugar

Artificial way to make language easier to read and write.

41.7 System F

Is parametric polymorphism in programming.

Extends the Lambda calculus by introducing ∀ (universal quantifier) over types.

41.7.1 *

Girard–Reynolds polymorphic lambda calculus
Girard-Raynolds

41.8 Tail call

Final evaluation inside the function. Produces the function result.

41.9 Thunk

Not evaluated calculation. Can be dragged around, until be lazily evaluated.

Table 41.1: Application memory structural parts

Storage of	Block name
All not currently processing data	Heap
Function call, local variables	Stack
Static and global variables	Static/Global
Instructions	Binary code

41.10 Application memory

When even Main invoked - it work in Stack, and called Stack frame. Stack frame size for function calculated when it is compiled.
When stacked Stack frames exceed the Stack size - stack overflow happens.

41.11 Turing machine

Mathematical model of computation that defines abstract Turing machine. Abstract machine which manipulates symbols on a strip of tape, according to a table of rules.

41.11.1 Turing complete

Set of action rules that can simulate any Turing machine.

41.11.1.1 *

Turing incomplete
Turing incompleteness
Turing completeness
Computationally universal

Chapter 42

Graph theory

42.1 Successor

Object that recieves the arrow.

42.1.1 Direct successor

Immidiate successor.

42.2 Predecessor

Object that sends arrow.

42.2.1 Direct predecessor

Immidiate predecessor.

42.3 Degree

Number of arrows of object.

42.3.1 Indegree

Number of ingoing arrows.

42.3.2 Outdegree

Number of outgoinf arrows.

42.4 Adjacency matrix

Matrix of connection of odjects `{-1,0,1}`.

42.4.0.1 InstanceSigs

Allow adding type signatures to type class function instance declaration.

42.5 Strongly connected

If every vertex in a graph is reachable from every other vertex.

It is possible to find all strongly connected components (and that way also test graph for strong connectivity), in linear time (`Θ(V+E)`).

Binary relation of being strongly connected is an equivalence relation.

42.5.1 *

Strongly-connected

42.5.2 Strongly connected component

Full strongly connected subgraph of some graph.

* of a directed graph G is a subgraph that is strongly connected, and has property: no additional edges or vertices from G can be included in the subgraph without breaking its property of being strongly connected.

42.5.2.1 *

SCC
Strongly connected components
Strongly-connected component
Strongly-connected components

Chapter 43

Linear

Values consumed once or not used.

`x^2` consumes `x` two times.

43.1 *

Linearity

Chapter 44

Stream

* an infinite sequence that forgets previous objects, and remembers only currently relevant objects.

$E \mid X \to (X \times A + 1)$, the set (or object) of streams on A (final coalgebra A_* of E).

`cycle` is one of stream functions.

```
a = (cycle [Nothing, Nothing, Just "Fizz"])
b = (cycle [Nothing, Nothing, Nothing, Nothing, Just "Buzz"])
```

Can be:

- indexed, timeless, with current object

- timed:

```
* [(timescale, event)]
* [(realtime, event)]
```

Has amalgamation with Functional Reactive Programming.

Chapter 45

Bisimulation

When systems have exact external behaviour so for observer they are the same.

Binary relation between state transition systems that match each other's moves.

45.1 *

Bisimilar

Chapter 46

Syntax tree

Tree of syntactic elements (each node denotes construct occurring in the source code) that represent the source code (or human language).

46.1 Abstract syntax tree

"Abstract" since does not represent every detail of the syntax (ex. parentheses), but rather concentrates on structure and content.

Widely used in compilers to check the code structure for accuracy and coherence.

46.1.1 *

AST

46.2 Concrete syntax tree

An ordered, rooted syntax tree that represents the syntactic structure of a string according to some context-free grammar.

"Concrete" since (in contrast to "abstract") - concretely reflects the syntax of the input language.

46.2.1 *

Parse tree
Derivation tree

Chapter 47

Domain specific language

Language design/fitted for particular domain of application. Mainly should be Turing incomplete, since general-purpose language implies Turing completeness.

47.1 *

Domain-specific language
DSL

47.2 Embedded domain specific language

DSL used inside outer language.

Two levels of embedding:

- Shallow: DSL translates into Haskell directly
- Deep: Between DSL and Haskell there is a data structure that reflects the expression tree, AKA stores the syntax tree.

47.2.1 *

eDSL

Chapter 48

Tagless-final

Method of embedding eDSL in a typed functional host language (Haskell). Alternative to the embedding as a (generalized) algebraic data type. For parsers of DLS expressions: (1/partial) evaluator, compiler, pretty printer, multi-pass optimizer.

* embedding is writing denotational semantics for the DSL in the host language.

Approach can be used iff eDSL is typed. Only well-typed terms become embeddable, and host language can implemen also a eDSL type system. Approach that eDSL code interpretations are type-preserving.

One of main pros of * - extensibility: implementation of DSL can be used to analyze/evaluate/transform/pretty-print/compile and interpreters can be extended to more passes, optimizations, and new versions of DSL while keeping/using/reusing the old versions.

Example fields of application: language-integrated queries, non-deterministic & probabilistic programming, delimiter continuation, computability theory, stream processsing, hardware description languages, generation of specialized numerical kernels, semantics of natural language.

GADT

Chapter 61

Order theory

Investigates in thepth the intuitive notion of order using binary relations.

61.1 Domain theory

Formalizes approximation and convergense.
Has close relation to Topology.

61.2 Lattice

Abstract structure that consists of partially ordered set, where every two elements have unique supremum and infinum. == * algebraic structure satisfying certain axiomatic identities.
* order-theory & algebraic.

61.3 Order

61.3.1 Preorder

$\mathrm{R}^{\mathrm{X} \to \mathrm{X}}$: Reflexive & Transitive:
aRa
$aRb, bRc \Rightarrow aRc$

Generalization of equivalence relations partial orders.

* Antisymmetric $\Rightarrow$ Partial ordering.
* Symmetric $\Rightarrow$ Equivalence.

61.3.1.1 *

Preordered

61.3.1.2 Total preorder

$\forall a, b : a \leq b \lor b \leq a \Rightarrow$ Total Preorder.

61.3.2 Partial order

A binary relation must be reflexive, antisymmetric and transitive.

Partial - not every elempents between them need to be comparable.

Good example of * is a genealogical descendancy. Only related people produce relation, not related do not.

61.3.2.1 *

Partial orders
Partially ordered set
Partially ordered sets
Poset
Posets

Chapter 63

Relation

63.1 Reflexivity

$R^{X \to X}, \forall x \in X : xRx$
Order theory: $a \leq a$

* - each element is comparable to itself.

Corresponds to Identity and Automorphism.

63.1.1 *

Reflexive
Reflexive relation

63.2 Irreflexivity

$R^{X \to X}, \forall x \in X : \nexists R(x, x)$

63.2.1 *

Anti-reflexive
Anti-reflexive relation
Irreflexive
Irreflexive relation

63.3 Transitivity

$\forall a, b, c \in X, \forall R^{X \to X} : (aRb \wedge bRc) \Rightarrow aRc$

* - the start of a chain of precedence relations must precede the end of the chain.

63.3.1 *

Transitive
Transitive relation

63.4 Symmetry

$\forall a, b \in X : (aRb \iff bRa)$

63.4.1 *

Symmetric
Symmetric relation

63.5 Equivalence

Reflexive	Symmetric	Transitive
$\forall x \in X, \exists R : xRx$	$\forall a, b \in X : (aRb \iff bRa)$	$\forall a, b, c \in X, \forall R^{X \to X} : (aRb \wedge bRc) \Rightarrow aRc$
$a = a$	$a = b \iff b = a$	$a = b, b = c \Rightarrow a = c$

63.5.1 *

Equivalent
Equivalent relation

63.6 Antisymmetry

$\forall a, b \in X : aRb, bRa \Rightarrow a = b \,\tilde{}\, aRb, a \neq b \Rightarrow \nexists bRa.$
Antisymmetry does not say anything about $R(a, a)$.

* - no two different elements precede each other.

63.6.1 *

Antisymmetric
Antisymmetric relation

63.7 Asymmetry

$\forall a, b \in X (aRb \Rightarrow \neg(bRa))$
* $\iff$ Antisymmetric $\wedge$ Irreflexive.
Asymmetry $\neq$ "not symmetric"
Symmetric $\wedge$ Asymmetric is only empty relation.

63.7.1 *

Asymmetric
Asymmetric relation

Chapter 64

Cryptomorphism

Equivalent, interconvertable with no loss of information.

64.1 *

Crypromorphic

Chapter 65

Lexically scoped type variables

Enable lexical scope for forall quantifier defined type variables

Implemented in ScopedTypeVariables

Chapter 66

Abstract data type

Several definitions here, reduce them.

Data type mathematical model, defined by its semantics from the user point of view, listing possible values, operations on the data of the type, and behaviour of these operations.

* class of objects whose logical behaviour is defined by a set of values and set of operations (analogue to algebraic structure in mathematics).

A specification of a data type like a stack or queue where the specification does not contain any implementation details at all, only the operations for that data type. This can be thought of as the contract of the data type.

66.1 *

AbsDT

Chapter 67

Concrete type

Fully defined type. Non-polymorphic type.

Chapter 68

Sexpr
Sexprs

Chapter 74

Polynomial

Expression consisting of:

- variables
- coefficients
- addition
- substraction
- multiplication (including positive integer variable exponentiation)

Polynomials form a ring. Polynomial ring.

74.1 *

Polynomials

Chapter 75

Data family

Indexed form of data and newtype definitions.

Chapter 76

Type synonym family

Indexed form of type synonyms.

Chapter 77

Indexed type family

* additional stucture in language that allows ad-hoc overloading of data types. AKA are to types as type class to methods.

Variaties:

- data family
- type synonym families

Defined by pattern matching the partial functions between types.
Associates data types by type-level function defined by open-ended collection of valid instances of input types and corresponding output types.

Normal type classes define partial functions from types to a collection of named values by pattern matching on the input types, while type families define partial functions from types to types by pattern matching on the input types. In fact, in many uses of type families there is a single type class which logically contains both values and types associated with each instance. A type family declared inside a type class is called an associated type.

77.1 *

Type family

Chapter 78

TypeFamilies

Allow use and definition of indexed type families and data families.

* are type-level programming.
* are overload data types in the same way that type classes overload functions.
* allow handling of dependent types. Before it Functional dependencies and GADTs were used to solve that.
* useful for generic programming, creating highly parametrised interfaces for libraries, and creating interfaces with enhanced static iformation (much like dependent types).

Implies: MonoLocalBinds, KindSignatures, ExplicitNamespaces

Two types of * are:

Chapter 79

Error

Mistake in the program that can be resolved only by fixing the program.

`error` is a sugar for `undefined`.

Distinct from Exception.

79.1 *

Errors

Chapter 80

Exception

Expected but irregular situation.

Distinct from Error. Also see Exception vs Error

80.1 *

Exceptions

Chapter 81

ConstraintKinds

Constraints are just handled as types of a particular kind (Constraint).
Any type of the kind Constraints can be used as a constraint.

- Anything which is already allowed in code as a constraint without *. Saturated applications to type classes, implicit parameter and equality constraints.

- Tuples, all of whose component types have kind Constraint.

```
type Some a = (Show a, Ord a, Arbitrary a) -- is of kind Constraint.
```

- Anything form of which is not yet known, but the user has declared for it to have kind Constraint (for which they need to import it from GHC.Exts):

```
Foo (f :: Type -> Constraint) = forall b. f b => b -> b -- is allowed
-- as well as examples involving type families:
type family Typ a b :: Constraint
type instance Typ Int  b = Show b
type instance Typ Bool b = Num b

func :: Typ a b => a -> b -> b
func = ...
```

Chapter 82

Specialisation

Turns ad hoc polymorphic function into compiled type-specific inmpementations.

82.1 *

Specialise
Specialize
Specialization

Chapter 83

Diagram

For categories C and J, a diagram of type J in C is a covariant functor $D : J \to C$.

Chapter 84

Cathegory theoretical presheaf

For categories C and J, a J-presheaf on C is a contravariant functor D : C → J.

Chapter 85

Topological presheaf

If X is a topological space, then the open sets in X form a partially ordered set Open(X) under inclusion. Like every partially ordered set, Open(X) forms a small category by adding a single arrow $U \to V$ if and only if $U \subseteq V$. Contravariant functors on Open(X) are called presheaves on X. For instance, by assigning to every open set U the associative algebra of real-valued continuous functions on U, one obtains a presheaf of algebras on X.

Chapter 86

Diagonal functor

The diagonal functor is defined as the functor from D to the functor category D^C which sends each object in D to the constant functor at that object.

Chapter 87

Limit functor

For a fixed index category J, if every functor $J \to C$ has a limit (for instance if C is complete), then the limit functor $C^J \to C$ assigns to each functor its limit. The existence of this functor can be proved by realizing that it is the right-adjoint to the diagonal functor and invoking the Freyd adjoint functor theorem. This requires a suitable version of the axiom of choice. Similar remarks apply to the colimit functor (which is covariant).

Chapter 88

Dual vector space

The map which assigns to every vector space its dual space and to every linear map its dual or transpose is a contravariant functor from the category of all vector spaces over a fixed field to itself.

Chapter 89

Fundamental group

Consider the category of pointed topological spaces, i.e. topological spaces with distinguished points. The objects are pairs (X, x0), where X is a topological space and x0 is a point in X. A morphism from (X, x0) to (Y, y0) is given by a continuous map $f : X \to Y$ with $f(x0) = y0$.

To every topological space X with distinguished point x0, one can define the fundamental group based at x0, denoted $\pi 1(X, x0)$. This is the group of homotopy classes of loops based at x0. If $f : X \to Y$ is a morphism of pointed spaces, then every loop in X with base point x0 can be composed with f to yield a loop in Y with base point y0. This operation is compatible with the homotopy equivalence relation and the composition of loops, and we get a group homomorphism from $\pi(X, x0)$ to $\pi(Y, y0)$. We thus obtain a functor from the category of pointed topological spaces to the category of groups.

In the category of topological spaces (without distinguished point), one considers homotopy classes of generic curves, but they cannot be composed unless they share an endpoint. Thus one has the fundamental groupoid instead of the fundamental group, and this construction is functorial.

Chapter 90

Algebra of continuous function

A contravariant functor from the category of topological spaces (with continuous maps as morphisms) to the category of real associative algebras is given by assigning to every topological space X the algebra C(X) of all real-valued continuous functions on that space. Every continuous map $f : X \to Y$ induces an algebra homomorphism $C(f) : C(Y) \to C(X)$ by the rule $C(f)(\varphi) = \varphi \circ f$ for every φ in C(Y).

Chapter 91

Tangent and cotangent bundle

The map which sends every differentiable manifold to its tangent bundle and every smooth map to its derivative is a covariant functor from the category of differentiable manifolds to the category of vector bundles.

Doing this constructions pointwise gives the tangent space, a covariant functor from the category of pointed differentiable manifolds to the category of real vector spaces. Likewise, cotangent space is a contravariant functor, essentially the composition of the tangent space with the dual space above.

Chapter 92

Group action / representation

Every group G can be considered as a category with a single object whose morphisms are the elements of G. A functor from G to Set is then nothing but a group action of G on a particular set, i.e. a G-set. Likewise, a functor from G to the category of vector spaces, $\mathrm{Vect}_{\mathrm{K}}$, is a linear representation of G. In general, a functor $G \to C$ can be considered as an "action" of G on an object in the category C. If C is a group, then this action is a group homomorphism.

Chapter 93

Lie algebra

Assigning to every real (complex) Lie group its real (complex) Lie algebra defines a functor.

Chapter 94

Tensor product

If C denotes the category of vector spaces over a fixed field, with linear maps as morphisms, then the tensor product $V \otimes W$ defines a functor $C \times C \to C$ which is covariant in both arguments.

Chapter 95

Forgetful functor

The functor U : Grp → Set which maps a group to its underlying set and a group homomorphism to its underlying function of sets is a functor.[8] Functors like these, which "forget" some structure, are termed forgetful functors. Another example is the functor Rng → Ab which maps a ring to its underlying additive abelian group. Morphisms in Rng (ring homomorphisms) become morphisms in Ab (abelian group homomorphisms).

Chapter 96

Free functor

Going in the opposite direction of forgetful functors are free functors. The free functor F : Set → Grp sends every set X to the free group generated by X. Functions get mapped to group homomorphisms between free groups. Free constructions exist for many categories based on structured sets. See free object.

Chapter 97

Homomorphism group

To every pair A, B of abelian groups one can assign the abelian group Hom(A, B) consisting of all group homomorphisms from A to B. This is a functor which is contravariant in the first and covariant in the second argument, i.e. it is a functor Abop $\times$ Ab $\rightarrow$ Ab (where Ab denotes the category of abelian groups with group homomorphisms). If f : A1 $\rightarrow$ A2 and g : B1 $\rightarrow$ B2 are morphisms in Ab, then the group homomorphism Hom(f, g): Hom(A2, B1) $\rightarrow$ Hom(A1, B2) is given by $\varphi \mapsto$ g $\circ$ φ $\circ$ f. See Hom functor.

Chapter 98

Representable functor

We can generalize the previous example to any category C. To every pair X, Y of objects in C one can assign the set Hom(X, Y) of morphisms from X to Y. This defines a functor to Set which is contravariant in the first argument and covariant in the second, i.e. it is a functor Cop $\times$ C $\rightarrow$ Set. If f : X1 $\rightarrow$ X2 and g : Y1 $\rightarrow$ Y2 are morphisms in C, then the group homomorphism Hom(f, g) : Hom(X2, Y1) $\rightarrow$ Hom(X1, Y2) is given by $\varphi \mapsto$ g $\circ$ φ $\circ$ f.

Functors like these are called representable functors. An important goal in many settings is to determine whether a given functor is representable.

Chapter 99

Corecursion

Chapter 100

Coinduction

proper definition

* dual to induction.
Generalises to corecursion.

Chapter 101

Initial algebra of an endofunctor

Chapter 102

Terminal coalgebra for an endofunctor

Citations

"One of the finer points of the Haskell community has been
its propensity for recognizing abstract patterns in code which
have well-defined, lawful representations in mathematics." (Chris Allen, Julie Moronuki - "Haskell Programming from First Principles" (2017))

Part V

Good code

Chapter 103

Good: Type aliasing

Use data type aliases to deferentiate logic of values.

Chapter 104

Good: Type wideness

Wider the type the more it is polymorphic, means it has broader application and fits more types.

The more constrained system has more usefulness.

Unconstrained means most flexible, but also most useless.

Chapter 105

Good: Print

```haskell
print :: Show a => a -> IO ()
print a = putStrLn (show a)
```

Chapter 106

Good: Fold

`foldr` spine recursion intermediated by the folding. Can terminate at any point.
`foldl` spine recursion is unconditional, then folding starts. Unconditionally recurses across the whole spine, if it infinite - infinitely.

Chapter 107

Good: Computation model

Model the domain and types before thinking about how to write computations.

Chapter 108

Good: Make bottoms only local

Chapter 109

Good: Newtype wrap is ideally transparent for compiler and does not change performance

Chapter 110

Good: Instances of types/type classes must go with code you write

Chapter 111

Good: Functions can be abstracted as arguments

Chapter 112

Good: Infix operators can be bind to arguments

Chapter 113

Good: Arbitrary

Product types can be tested as a product of random generators.
Sum types require to implement generators with separate constructors, and picking one of them, use `oneof` or `frequency` to pick generators.

Chapter 114

Good: Principle of Separation of concerns

Chapter 115

Good: Function composition

In Haskell inline composition requires:

```
h.g.f $ i
```

Function application has a higher priority than composition. That is why parentheses over argument are needed.
This precedence allows idiomatically compose partially applied functions.

But it is a way better then:

```
h (g (f i))
```

Chapter 116

Good: Point-free

Use Tacit very carefully - it hides types and harder to change code where it is used.
Use just enough Tacit to communicate a bit better. Mostly only partial point-free communicates better.

116.1 Good: Point-free is great in multi-dimentions

BigData and OLAP analysis.

Chapter 117

Good: Functor application

Function application on n levels beneath:

```
(fmap . fmap) function twoLevelStructure
```

How `fmap . fmap` typechecks:

```
(.)         :: (b -> c) -> (a -> b) -> a -> c
fmap        :: Functor f => (m -> n) -> f m -> f n
fmap        :: Functor g => (x -> y) -> g x -> g y

fmap . fmap :: (Functor f, Functor g)
              => ((g x -> g y) -> f . g x -> f . g y)
              -> ((  x ->   y) ->     g x  ->    g y)
              -> (   x ->   y) -> f . g x -> f . g y
fmap . fmap ::   (x     ->   y) -> f . g x -> f . g y
```

Chapter 118

Good: Parameter order

In functions parameter order is important.
It is best to use first the most reusable parameters.
And as last one the one that can be the most variable, that is important to chain.

Chapter 119

Good: Applicative monoid

There can be more than one valid Monoid for a data type. &&
There can be more than one valid Applicative instance for a data type. ->
There can be differnt Applicatives with different Monoid implementations.

Chapter 120

Good: Creative process

120.1 Pick phylosophy principles one to three the more - the harder the implementation

120.2 Draw the most blurred representation

120.3 Deduce abstractions and write remotely what they are

120.4 Model of computation

120.4.1 Model the domain

120.4.2 Model the types

120.4.3 Think how to write computations

120.5 Create

Chapter 121

«<Good: About operators (<$) (**>) (<*) (») »>

Where character is not present - discard the according processing of a parameter.
(») is an exception, it does the reverse. ignores the first parameter.

Chapter 122

Good: About functions like {mapM, sequence}_

Trailing _ means ignoring the result.

Chapter 123

Good: Guideliles

123.1.3 Code

123.1.3.1 Try to stay closer to portable (Haskell98) code

123.1.3.2 Try make lines no longer 80 chars

123.1.3.3 Last char in file should be newline

123.1.3.4 Symbolic infix identifiers is only library writer right

123.1.3.5 Every function does one thing.

Chapter 124

Good: Use Typed holes to progress the code

Typed holes help build code in complex situations.

Chapter 125

Good: Haskell allows infinite terms but not infinite types

That is why infinite types throw infinite type error.

Chapter 126

Good: Use type sysnonims to differ the information

Even if there is types - define type synonims. They are free.
That distinction with synonims, would allow TypeSynonymInstances, which would allow to create a diffrent type class instances and behaviour for different information.

Chapter 127

«<Good: Control.Monad.Error -> Control.Monad.Except»>

Chapter 128

Good: Monad OR Applicative

128.0.1 Start writing monad using 'return', 'ap', 'liftM', 'liftM2', '»' instead of 'do','»='

If you wrote code and really needed only those - move that code to Applicative.

```
return -> pure
ap -> <*>
liftM -> liftA -> <$>
>> -> *>
```

128.0.2 Basic case when Applicative can be used

Can be rewriten in Applicative:

```
func = do
  a <- f
  b <- g
pure (a, b)
```

Can't be rewritten in Applicative:

```
somethingdoSomething' n = do
a <- f n
b <- g a
pure (a, b)
```

(f n) creates monadic structure, binds ot to *a* wich is consumed then by g.

128.0.3 Applicative block vs Monad block

With Type Applicative every condition fails/succseeds independently. It needs a boilerplate data constructor/value pattern matching code to work. And code you can write only for so many cases and types, so boilerplate can not be so flexible as Monad that allows polymorphism.
With Type Monad computation can return value that dependent from the previous computation result. So abort or dependent processing can happen.

Chapter 129

Good: Haskell Package Versioning Policy

Version policy and dependency management.

[width=.9]Good$_{c}ode/pvp - decision - tree_{2}019 - 06 - 17_{1}5 - 49 - 21$

129.1 *

PVP
Good: PVP

Chapter 130

Good: Linear type

Linear types are great to control/minimize resource usage.

Chapter 131

Good: Exception vs Error

Many languages and Haskell have it all mixup. Here is table showing what belongs to one or other in standard libraries:

Exception	Prelude.catch, Control.Exception.catch, Control.Exception.try, IOError, Control.Monad.Error
Error	error, assert, Control.Exception.catch, Debug.Trace.trace

Chapter 132

Good: Let vs. Where

`let ... in ...` is a separate expression. In contrast, `where` is bound to a surrounding syntactic construct (namespace).

Chapter 133

Good: RankNTypes

Can powerfully synergyze with ScopedTypeVariables.

Chapter 134

Good: Orphan type instance

Practice to address orphan instances:

Does type class or type defined by you:

Type class	Type	Recommendation
	✓	{Type, instance} in the same module
✓		{Typeclass & instance} in the same module
		{Define newtype wrap, its instances} in the same module

Chapter 135

Good: Smart constructor

Only proper smart constructors should be exported. Do not export data type constructor, only a type.

Chapter 136

Good: Thin category

In * all morphisms are epimorphisms and monomorphisms.

Chapter 137

Good: Recursion

Writing/thinking about recursion:

a. Find the base cases, om imput of which the answer can be provided right away. There is mosly one base case, but sometimes there can be several of them. Typical base cases are: zero, the empty list, the empty tree, null, etc.

b. Do inductive case. The recursive invocation. The argument of a recursive call needs to be smaller then the current argument. So it would be gradually closer to the base case. The idea is that processes eventually hits the base case.

Simple functional application is used in the recursion.
Assume that the functions would return the right result.

Chapter 138

Good: Monoid

`<>`:
Sets - union.
Maps - left-biased union.
Number - `Sum`, `Product` form separate monoid categories.

Chapter 139

Good: Free monad

The main case of usage of Free monads in Haskell:

Start implementation of the monad from a Free monad, drafting the base monadic operations, then add custom operations.

Gradually build on top of Free monad and try to find homomorphisms from monad to objects, and if only objects are needed - get rid of the free monad.

Chapter 140

Good: Use mostly where clauses

Chapter 141

Good: Where clause is in a scope with function parameters

Chapter 142

Good: Strong preference towards pattern matching over {head, tail, etc.} functions

`head` and `tail` and alike functions are often partial (unsafe) funcitons.

Chapter 143

Good: Patternmatching is possible on monadic bind in do

Example:

```haskell
instance (Monad m) => Functor (StateT s m) where
  fmap f m = StateT $ \s -> do
    (x, s') <- runStateT m s   -- Here is a pattern matching bind
    return (f x, s')
```

Chapter 144

Good: Applicative vs Monad

Giving not `Monad` but `Applicative` requirement allows parralel computation, but if there should be a chaining of the intemidiate state - it must be monadic.

Chapter 145

Good: StateT, ReaderT, WriterT

`Reader` trait: `(r ->)`.

`Writer` trait: `(a, w)`.

`State` trait is combination of both:

```
newtype StateT s m a =
  StateT  { runStateT  :: s -> m (a, s) }

newtype ReaderT r m a =
  ReaderT { runReaderT :: r -> m   a    }

newtype WriterT w m a =
  WriterT { runWriterT ::      m (a, w) }
```

`State` trait fully replaces `writer`.

Chapter 146

Good: Working with MonadTrans and lift

From the `lift . pure = pure` follows that `MonadTrans` type can have a `pure` defined with `lift`.

Stacking of `MonadTrans` monads can result in a lot of chained `lift` and unwraps. There is many ways to cope with that but the most robust and common is to abstract representation with `newtype` on the `Monad` stack. This can reduce caining or remove the manual lifting withing the Monad.
For perfect combination for contributors to be able to extend the code - keep the `Internal` module that has a raw representation.

Chapter 147

Good: Don't mix Where and Let

`let` and `where` create a recursive set of definitions with can explode, don't mix them togather in code.

Chapter 148

Good: Where vs. Let

Let is self-recursive lazy pattern. It is checked and errors only at execution time. Binds only inside expression it is binded to.

Where is a part of definition, scoped over definition implemetations and guards, not self-recursive.

Chapter 149

Good: The proper nature algorithm that models behaviour of many objects is computation heavy

> God does not care about our mathematical difficulties. He integrates empirically.

One who is found of mathematical meaning loves to apply it. But if we implement the "real" algorithms behind nature processes, we face the need to go through the computations of laws of all particles.

Computation of nature is always a middle way between ideal theory behaviour and computation simplification.

Chapter 150

Good: In Haskell parameters bound by lambda declaration instantiate to only one concrete type

Because of let-bound polymorphism:

This is illegal in Haskell:

```
foo :: (Int, Char)
foo = (\f -> (f 1, f 'a')) id
```

Lambda-bound function (i.e., one passed as argument to another function) cannot be instantiated in two different ways, if there is a let-bound polymorphism.

Chapter 151

Good: Instance is a good structure to drew a type line

Instances for data type can differentiate by constraints & types of arguments. So instance can preserve type boundary, and data type declaration can stay very polymorphic. If the need to extend the type boundaries arrive - the instances may extend, or new instances are created, while used data type still the same and unchanged.

Chapter 152

Good: MTL vs. Transformers

Default ot `mtl`.

`Transformers` is Haskell-98, doesn't have funcitonal dependencies, lacks the monad classes, has manual lift of operations to the composite monad.

`MTL` extends `trasformers`, providing more instances, features and possibilities, may include alternative packages features as `mtl-tf`.

Part VI

Bad code

Chapter 153

Bad pragma

153.1 Bad: Dangerous LANGUAGE pragma option

- DatatypeContexts
- OverlappingInstances
- IncoherentInstances
- ImpredicativeTypes
- AllowAmbigiousTypes
- UndecidableInstances - often

Part VII

Useful functions to remember

Chapter 154

Prelude

```
enumFromTo
enumFromThenTo
reverse
show :: Show a => a -> String
flip
sequence - Evaluate each monadic action in the structure from left to right, and collect the resu
:sprint - show variables to see what has been evaluated already.
minBound - smaller bound
maxBound - larger bound
cycle :: [a] -> [a] - indefinitely cycle s list
repeat - indefinit lis from value
elemIndex e l - return first index, returns Maybe
fromMaybe (default if Nothing) e ::Maybe a -> a
lookup :: Eq a => a -> [(a, b)] -> Maybe b
```

154.1 Ord

compare

154.2 Calc

div - always makes rounding down, to infinity
divMod - returns a tuple containing the result of integral division and modulo

154.3 List operations

```
concat - [ [a] ] -> [a]
elem x xs - is element a part of a list
zip :: [a] -> [b] -> [(a, b)] - zips two lists together. Zip stops when one list runs out.
zipWith :: (a -> b -> c) -> [a] -> [b] -> [c] - do the action on corresponding elements of list a
```

Chapter 155

Data.List

```
intersperse :: a -> [a] -> [a]  -  gets the value and incerts it between values in array
nub - remove duplicates from the list
```

Chapter 156

Data.Char

```
ord (Char -> Int)
chr (Int -> Char)
isUpper (Char -> Bool)
toUpper (Char -> Char)
```

Chapter 157

QuickCheck

```
quickCheck :: Testable prop => prop -> IO ()
```

```
quickCheck . verbose - run verbose mode
```

Part VIII

Tools

Chapter 158

ghc-pkg

List installed packages:

```
ghc-pkg list
```

Chapter 159

Search over the Haskell packages code: Codesearch from Aelve

https://codesearch.aelve.com/

Chapter 160

Integration of NixOS/Nix with Haskell IDE Engine (HIE) and Emacs (Spacemacs)

160.1 1. Install the Cachix: https://github.com/cachix/cachix

160.2 2. Installation of HIE: https://github.com/infinisil/all-hies/#cached-builds

160.2.1 2.1. Provide cached builds

```
cachix use all-hies
```

160.2.2 2.2.a. Installation on NixOS distribution:

```
{ config, pkgs, ... }:

let

  all-hies = import (fetchTarball "https://github.com/infinisil/all-hies/tarball/master") {};

in {
  environment.systemPackages = with pkgs; [

    (all-hies.selection { selector = p: { inherit (p) ghc865 ghc864; }; })

  ];
}
```

Insert your GHC versions.

Switch to new configuration:

```
sudo -i nixos-rebuild switch
```

160.2.3 2.2.b. Installation with Nix package manager:

```
nix-env -iA selection --arg selector 'p: { inherit (p) ghc865 ghc864; }' -f 'https://github.com/i
```

Insert your GHC versions.

160.3 3. Emacs (Spacemacs) configuration:

```
  dotspacemacs-configuration-layers
  '(

    auto-completion

    (lsp :variables
         default-nix-wrapper (lambda (args)
                              (append
                               (append (list "nix-shell" "-I" "." "--command" )
                                       (list (mapconcat 'identity args " "))
                                       )
                               (list (nix-current-sandbox))
                               )
                              )

         lsp-haskell-process-wrapper-function default-nix-wrapper
         )

    (haskell :variables
             haskell-enable-hindent t
             haskell-completion-backend 'lsp
             haskell-process-type 'cabal-new-repl
             )

  )

   dotspacemacs-additional-packages '(
                                      direnv
                                      nix-sandbox
                                      )

(defun dotspacemacs/user-config ()

  (add-hook 'haskell-mode-hook 'direnv-update-environment) ;; If direnv configured

  )
```

Where:

`auto-complettion` configures `YASnippet`.

`nix-sandbox` (https://github.com/travisbhartwell/nix-emacs) has a great helper functions. Using `nix-current-sandbox` function in `default-nix-wrapper` that used to properly configure `lsp-haskell-process-wrapper-function`.

Configuration of the `lsp-haskell-process-wrapper-function default-nix-wrapper` is a key for HIE to work in `nix-shell`

Inside `nix-shell` the `haskell-process-type 'cabal-new-repl` is required.

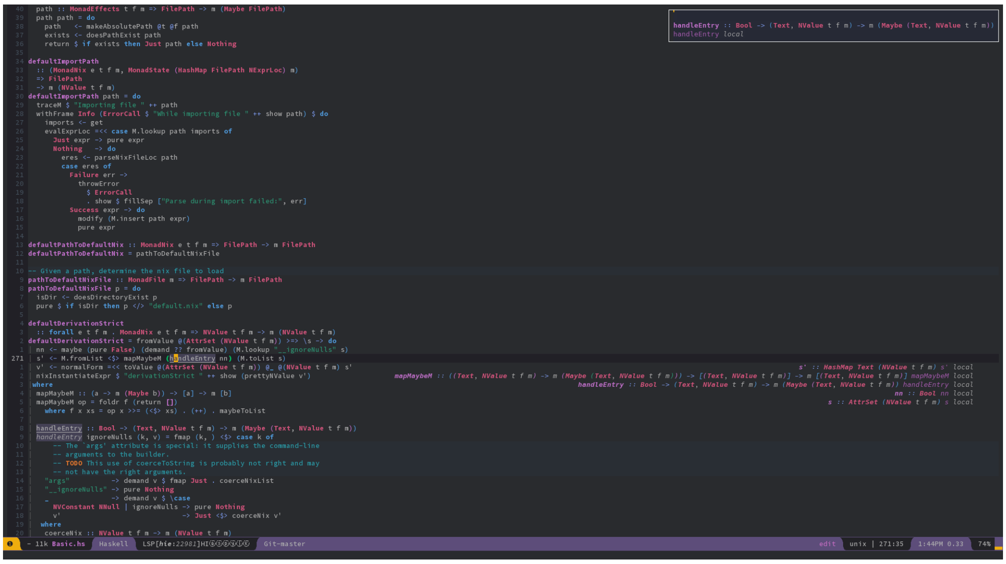
Configuration was reassembled from: *https://github.com/emacs-lsp/lsp-haskell/blob/8f2dbb6e827b1adce6360c56f795f29ecff1d7f6/lsp-haskell.el#L57* *& its authors config:* *[[https://github.com/sevanspowell/dotfiles/blob/master*.spacemacs]]/

Refresh Emasc.

160.4 4. Open the Haskell file from a project

Open system monitor, observe the process of environment establishing, packages loading & compiling.

160.5 5. Be pleased writing code



Now, the powers of the Haskell, Nix & Emacs combined. It's fully in your hands now. Be cautious - you can change the world.

160.6 6. (optional) Debugging

a. If recieving sort-of:

```
readCreateProcess : cabal-helper-wrapper failure
```

HIE tries to run `cabal` operations like on the non-Nix system. So it is a problem with detection of `nix-shell` environment, running inside it.

a. If HIE keeps getting ready, failing & restarting - check that the projects `ghc --version` is declared in your `all-hie` NixOS configuration.

Chapter 161

Debugger

Provides:

- set a breakpoints
- observe step-by-step evaluation
- tracing mode

Breakpoints

```
:break 2
  :show breaks
  :delete 0
:continue
```

Step-by-step

```
:step main
```

List information at the breakpoint

```
:list
```

What been evaluated already

```
:sprint name
```

Chapter 162

GHCID

Commands to run the compile/check loop:

`cabal` > `3.0` command:

```
ghcid --command='cabal v2-repl --repl-options=-fno-code --repl-options=-fno-break-on-exception --
```

`cabal` < `3.0` command:

```
ghcid --command='cabal new-repl --ghc-options=-fno-code --ghc-options=-fno-break-on-exception --g
```

`nix-shell cabal` > `3.0` command:

```
nix-shell --command 'ghcid --command="cabal v2-repl --repl-options=-fno-code --repl-options=-fno-
```

`nix-shell cabal` < `3.0` command:

```
nix-shell --command 'ghcid --command="cabal new-repl --ghc-options=-fno-code --ghc-options=-fno-b
```

Part IX

Libs

Chapter 163

Exceptions

163.1 Exceptions - optionally pure extensible exceptions that are compatible with the mtl

163.2 Safe-exceptions - safe, simple API equivalent to the underlying implementation in terms of power, encourages best practices minimizing the chances of getting the exception handling wrong.

163.3 Enclosed-exceptions - capture exceptions from the enclosed computation, while reacting to asynchronous exceptions aimed at the calling thread.

Chapter 164

Memory management

164.1 membrain - type-safe memory units

Chapter 165

Parsers - megaparsec

Chapter 166

CLIs - optparse-applicative

Chapter 167

HTML - Lucid

Chapter 168

Web applications - Servant

Chapter 169

IO libraries

169.1 Conduit - practical, monolythic, guarantees termination return

169.2 Pipes + Pipes Parse - modular, more primitive, theoretically driven

Chapter 170

JSON - aeson

Chapter 171

Backpack

On 1-st compilation - * analyzes the abstract signatures without loading side modules, doing the type check with assumption that modules provide right type signatures, the process does not emitt any binary code and stores the intermediate code in a special form that allows flexibily connect modules provided. Which allows later to compile project with particular instanciations of the modules. Major work of this process being done by internal Cabal * support and * system that modifies the intermediate code to fit the module.

Part X

Drafts

Chapter 172

Exception handling

Exception must include all context information that may be useful.
Store information in a form for further probable deeper automatic diagnostic.
Sensitive data/dummies for it - can be useful during development.
Sensitive data should be stripped from a program logging & exceptions.
Exception system should be extendable, data storage & representation should be easily extendable.
Exception system should allow easy exaustive checking of errors, since the different errors can happen.
Exception system should be automatically well-documented and transparent.
Exception system should have controllable breaking changes downstream.
Exception system should allow complex composite (sets) exceptions.
Exception system should be lightweight on the type signatures of other functions.
Exception system should automate the collection of context for a exception.
Exception system should have properties and according functions for particular types of errors.

`String` is simple and convinient to throw exception, but really a mistake because it the most cumbersome choise:

- Any Exception instance can be converted to a `String` with either `show` or `displayException`.

- Does not include key debugging information in the error message.

- Does not allow developer to access/manage the Exception information.

- Exception messages need to be constructed ahead of time, it can not be internationalized, converted to some data/file format.

- Exception can have a sensitive information that can be useful for developer during work, but should not be logged/shown to end-user. Stripping it from `Strings` in the changing project is a hard task.

- Impossible to rely on this representation for further/deeper inspection.

- Impossible to have exhaustive checking - no knowledge no check, no warning if some cases are not handled.

Universal exception type:

- Able to inspect every possible error case with pattern match.
- Self-documenting. Shows the hierarchical system of all exceptions.
- Transparent. Ability to discern in current situation what exceptions can happen
- New exception constructor causes breaking change to downstream.
- Wrongly implies completeness. Untreated Errors can happen, different exception can arrive from the outside code.

Sum type must be separate, and product type structure over it.
Separate exception type of

Individual exception types:

- Writing & seing & working with exactly what will go wrong because there is only one possible error for this type of exception. Pattern match happens only onconditions, constructors that should happen.
- Knowledge what exectly goes wrong allows wide usage of Either.
- It is hard to handle complex exceptions in the unitary system. Real wrorld can return not a particular case, but a set of cases {object not found, path is unreachable, access is denied}.
- Type signatures grow, and even can become complex, since every case of exception has its own type.
- Impure `throw` that users can/should use for your code must account for all your exception types.

Abstract exception type:
Exception type entirely opague and inspectable only by accessor functions.

- Updating the internals without breaking the API
- Semi-automates the context of exception with passing it to accessors.
- Predicates can be applied to more than one constructor. Which are properties that allows to make complex exceptions much easier to handle.
- Not self-documenting.

- Possible options by design are hidden from the downstream, documentation must be kept.

- When you change the exception handling/throwing errors it does not shows to the downstream.

Composit approach:
Provide the set of constructors and also a set of predicates and set of accessors.
Use pattern synonyms to provide a documented accessor set without exposing internal data type.

In GHC 8.8 the change was made:

> The fail method of Monad has been removed in favor of the method of the same name in the MonadFail class.
>
> MonadFail(..) is now exported from the Prelude and Control.Monad modules.
> The MonadFailDesugaring language extension is now deprecated, as its effects are always enabled.

So:

```
import           Control.Monad.Fail
...
class MonadFail m => MonadFile m
...
-- use error instead of fail
Nothing     -> error ("Message " <> show x)
```

Chapter 173

Constraints

Very strong Haskell type system makes possible to work with code from the top down, an axiomatic semantics approach, from constraints into types.

- Helps to form the type level code (aka join points of the code).
- Uses the piling up of constraints/types information. At some point pick and satisfy constraints, can be done one at a time.
- Provides hints through type level formulation for term level calculations, does not formulate the term level.
- Tedious method (a lot of boilerplate and rewriting it) but pretty simple and relaxing.
- Set of constraints.
- When it is needed or convenient, single constraint gets a little more realistically concrete/abstracted.

Main type detail annotation thread can happen in `main` or special wrapper function, localization is inside functions.

a. Rest of constraints set shifts to source type.

3.a. For the class handled or known how to handle - writte a base case instance description.

```
instance (Monad m) => MonadReader r (ReaderT r m)
```

3.b. For others write recursive instance descriptions:

All other unsolved constraints move into the source polymorphic variable.

```
instance (MonadError e m) => MonadError e (ReaderT r m)
instance (MonadState s m) => MonadState s (ReaderT r m)
```

a. Repeat from 1 until considered done.

b. Code condensed into terse form.

`MonadError` constraints is `IOException`, not for the `String`. `IOException` vs `String`.

Reverse pluck `MonadReader` constraint with `runReader` on the object.

`MonadState` - `StateT`

Chapter 174

Monad transformers and their type classes

Chapter 175

Layering monad transformers

Different layering of the same monad transformers is functionality is the same, but the form is different. Surrounding handling functions would need to be different.

Chapter 176

Hoogle

176.1 Search

Text search (case insensitive):

- `a`
- `map`
- `con map`

Type search:

- `:: a`
- `:: a -> a`

Text & type:

=**id** a -> a=

176.2 Scope

176.2.1 Default

Scope is Haskell Platform (and Haskell keywords).

All Hackage packages are available to search with:

176.2.2 Hierarchical module name system (from big letter):

- `fold +Data.Map` finds results in the `Data.Map` module

- `file -System` excludes results from modules such as `System.IO`, `System.FilePath.Windows` and `Distribution.System`

176.2.3 Packages (lower case):

- `mode +platform`
- `mode +cmdargs` (only)
- `mode +platform +cmdargs`
- `file -base` (Haskell Platform, excluding the "base" package)

Chapter 177

ST-Trick monad

ST is like a lexical scope, where all the variables/state disappear when the function returns
https://wiki.haskell.ohttps://www.schoolofhaskell.com/school/to-infinity-and-beyond/older-but-still-interesting/deamortized-strg/Monad/ST
https://dev.to/jvanbruegge/what-the-heck-is-polymorphism-nmh

177.1 *

ST-Trick

Chapter 178

Either

Allows to separate and preserve information about happened, ex. error handling.

178.1 *

Either data type

Chapter 179

Inverse

a. Inverse function

b. In logic: $P \to Q \Rightarrow \neg P \to \neg Q$, & same for category duality.

c. For operation: element that allows reversing operation, having an element that with the dual produces the identity element.

d. See Inversion.

Chapter 180

Inversion

a. Is a permutation where two elements are out of order.

b. See Inverse

Chapter 181

Inverse function

$f_{x \to y} \circ (f_{x \to y})^{-1} = 1_x$

* $\iff$ function is bijective.
Otherwise - partial inverse

Chapter 182

Inverse morphism

For $f : x \to y$:
$\exists g \; : \; g \circ f = 1^x$ - g is left inverse of f.
$\exists g \; : \; f \circ g = 1^y$ - g is right inverse of f.

Chapter 183

Partial inverse

* when function is now bijective. When bijective see inverse function.

Chapter 184

PatternSynonyms

Enables pattern synonym declaration, which always begins with the `pattern` word.
Allows to abstract-away the structures of pattern matching.

184.1 *

Pattern synonym
Pattern synonyms

Chapter 185

GHC debug keys

185.1 -ddump-ds

Dump desugarer output.

185.1.1 *

Desugar
GHC desugar

Chapter 186

GHC optimize keys

186.1 -foptimal-applicative-do

$O(n^3)$
Always finds optimal reduction into <*> for ApplicativeDo do notation.

Chapter 187

Computational trinitarianism

Taken from: https://ncatlab.org/nlab/show/computational+trinitarianism

Under the statements:

- propositions as types
- programs as proofs
- relation between type theory and category theory

the following notions are equivalent:

== proposition proof (Logic)

== generalized element of an object (Category theory)

== typed program with output (Type theory & Computer science)

Table 187.1: Computational trinitarianism

Logic	Category theory	Type theory
true	terminal object/(-2)-truncated object	h-level 0-typ
false	initial object	empty type
proposition	(-1)-truncated object	h-propositio
proof	generalized element	program
cut rule	composition of classifying morphisms / pullback of display maps	substitution
cut elimination for implication	counit for hom-tensor adjunction	beta reducti
introduction rule for implication	unit for hom-tensor adjunction	eta conversi
logical conjunction	product	product typ
disjunction	coproduct ((-1)-truncation of)	sum type (b
implication	internal hom	function typ
negation	internal hom into initial object	function typ
universal quantification	dependent product	dependent p
existential quantification	dependent sum ((-1)-truncation of)	dependent s
equivalence	path space object	identity type
equivalence class	quotient	quotient typ

187.1 *

Trinitarism

Chapter 188

Techniques functional programming deals with the state

188.1 Minimizing

Do not rely on state, try not to change the state. Use it only when it is very necessary.

188.2 Concentrating

Concentrate the state in one place.

188.3 Deferring

Defer state to the last step of the program, or to external system.

Chapter 189

Monadic Error handling

```
(>>=) :: m a -> (a -> m b) -> m b -- λA.E ∨ A - computes and drops if error value happens.
catch :: c a -> (e -> c a) -> c a -- λE.E ∨ A - handles "errors" as "normal" values and stops whe
```

Chapter 190

Functions

Total function uses domain fully, but takes only part of the codomain.
Function allows to collapse domain values into codomain value. Meaning the function allows to loose the information.
So total function is a computation that looses the information or into bigger codomains.
That is why the function has a directionality, and inverse total process is partially possible.

Directionality and invertability are terms.

Chapter 191

Void

Emptiness.

Can not be grasped, touched.

A logically uninhabited data type.

(Since basis of logic is tautologically True and Void value can not be addressed - there is a logical paradox with the Void).

Is an object includded into the Hask category, since:

```
:t (id :: Void -> Void)
(id :: Void -> Void) :: Void -> Void
```

`id` for it exists.

Type system corresponds to constructive logic and not to the classical logic.
Classical logic answers the question "Is this actually true".
Constuctive (Intuitionistic) logic answers the question "Is this provable".

Also has functions:

```
-- Represents logical principle of explosion: from falsehood, anything follows.
absurd :: Void -> a

-- If Functor holds only Void - it holds no values.
vacuous :: Functor f => f Void -> f a

-- If Monad holds only Void - it holds no values.
vacuousM :: Monad m => m Void -> m a
```

Design pattern: use polymorphic data types and Void to get rid of possibilities when you need to.

191.1 *

Nothing, Haskell expressions can't return Void.

Also see: Maybe.

Chapter 192

Constructive proof

Method of proof that demonstrates the existence of a mathematical object by creating or providing a method for creating the object.

Chapter 193

Intuitionistic logic

Proposition considered `True` due to direct evidence of existence through constructive proof using Curry-Howard isomorphism.

* does not include classic logic fundamental axioms of the excluded middle and double negation elimination. Hense * is weaker then classical logic. Classical logic includes *, all theorems of * are also in classical logic.

193.1 *

Constructive logic

Chapter 194

Principle of explosion

From asserted statement that contains contradiction - anything can be proven.
Ancient principle of logic. Both in classical & intuitionistic logic.

194.1 *

Ex falso quodlibet
Ex falso sequitur quodlibet
EFG
Ex contradictione quodlibet
Ex contradictione sequitur quodlibet
ECQ
Deductive explosion
Pseudo-Scotus

Chapter 195

Universal property

A property of some construction which boils down to (is manifestly equivalent to) the property that an associated object is a universal initial object of some (auxiliary) category.

Chapter 196

Yoneda lemma

Allows the embedding of any category into a category of functors (contravariant set-valued functors) defined on that category. It also clarifies how the embedded category, of representable functors and their natural transformations, relates to the other objects in the larger functor category.

The Yoneda lemma suggests that instead of studying the (locally small) category C $\{\{\{C\}\}\}\mathcal{C}, oneshouldstudythecateg$

Chapter 197

Monoidal category, functoriality of ADTs, Profunctors

Category equipped with tensor product.

<>

wich is a functor for *.

Set category can be monoidal under both product (having terminal object) or coproduct (having initial object) operations, if according operation exist for all objects.

Any one-object category is *.

$(a, ()) \sim a$ up to unique isomorphism, which is called Lax monoidal functor.

Product and coproduct are functorial, so, since:
Algebraic data type construction can use:

- Type constructor
- Data constructor
- Const functor
- Identity functor
- Product
- Coproduct

Any algebraic data type is functorial.

Chapter 198

Const functor

Maps all objects of source category into one (fixed) object of target category, and all morphisms to identity morphism of that fixed object.

```haskell
instance Functor (Const c)
 where
  fmap :: (a -> b) -> Const c a -> Const c b
  fmap _ (Const c) = Const c
```

In Category theory denoted:

Δ

Last type parameter that bears the target type of lifted function (`b`) and is a proxy type.

Analogy: the container that allways has an object attached to it, and everything that is put inside - changes the container type accordingly, and dissapears.

Chapter 199

Arrow in Haskell

```
(->) a b = a -> b
```

Functorial in the last argument & called Reader functor.

```
newtype Reader c a = Reader (c -> a)
```

```
  fmap = ( . )
```

Chapter 200

Contravariant functor

```haskell
fmap :: (a -> b) -> Op c a -> Op c b
                (a -> c) -> (b -> c)
```

$$
\begin{tikzcd}
a \arrow[r] \arrow[dr] & b \arrow[d, dashed] \\
 & c
\end{tikzcd}
$$

$(a \to b)^{C} = (a \leftarrow b)^{C^{op}}$

```haskell
class Contravariant f
 where
  contramap :: (b -> a) -> (f a -> f b)
```

$$
\begin{tikzcd}
a \arrow[r] \arrow[dr] & b \arrow[d, dashed, "contravariant"] \\
 & c
\end{tikzcd}
$$

If arrows does not commute Contravatiant funtor anyway allows to construct transformation between these such arrows to other arrow.

Chapter 201

Profunctor

```
(->) a b
```

$C^{op} \times C \to C$

It is called profunctor.

```
dimap :: (a' -> a) -> (b -> b') -> p a b -> p a' b'
```

So, profunctor in case of arrow:

$$\begin{tikzcd}
a \arrow[d, "h"] & a' \arrow[l, "f"] \arrow[d, dashed, "profunctor"] \\
b \arrow[r, "g"] & b'
\end{tikzcd}$$

```
dimap :: (a' -> a) -> (b -> b') -> p a b -> p a' b'
dimap ::    f           g       -> (a -> b) -> (a' -> b')
dimap ::    f           g       ->    h     -> (a' -> b')
dimap = g . h . f
```

It is contravariant functor in the first argument, and covariant functor in the second argument.

```
dimap id <==> fmap
(flip dimap) id <==> contramap
```

Chapter 202

Functor-Applicative-Monad Proposal

Well known event in Haskell history: https://github.com/quchen/articles/blob/master/applicative_monad.md.

Math justice was restored with a RETroactive CONtinuity. Invented in computer science term Applicative (lax monoidal functor) become a superclass of Monad.

& that is why:

- `return = pure`
- `ap = <*>`
- `>> = *>`
- `liftM = liftA = fmap`
- `liftM* = liftA*`

Also, a side-kick - Alternative became a superclass of MonadPlus. Hense:

- `mzero = empty`
- `mplus = (<|>)`

Chapter 203

Haskell-98

203.1 Old instance termination rules

a. ∀ class constraint (C t1 .. tn):
   1.1. type variables have occurances $\leq$ head
   1.2. constructors+variables+repetitions $<$ head
   1.3. ¬ type functions (type func application can expand to arbitrary size)

b. ∀ functional dependencies, $\langle \text{tvs} \rangle_{\text{left}} \rightarrow \langle \text{tvs} \rangle_{\text{right}}$, of the class, every type variable in $S(\langle \text{tvs} \rangle_{\text{right}})$ must appear in $S(\langle \text{tvs} \rangle_{\text{left}})$, where S is the substitution mapping each type variable in the class declaration to the corresponding type in the instance head.

Liturgy

$\lambda\varepsilon\iota\tau$ <- $\lambda\alpha$´ς *Laos* the people
$o\upsilon\rho\gamma$´ς <- $\rho\gamma o$ *ergon* work
$\lambda\varepsilon\iota\tau o\upsilon\rho\gamma$´$\alpha$ *leitourgia* giving back to the community

The life is beautiful.
For all humans that make the life have more uniqueness.

This study would not be possible without mathematicians, Haskellers, scientists, creators, contributors. These people are the most fascinating in my life.

Special accolades for the guys at Serokell. They were the force that got me inspired & gave resources to seriously learn Haskell and create this pocket guide.
